In conclusion, this research paper explored the application of IoT-based energy management using the bidirectional visitor counter technique. The findings of this study demonstrate the effectiveness and potential benefits of integrating IoT technologies with the bidirectional visitor counter technique in optimizing energy consumption and promoting sustainability. The bidirectional visitor counter technique provided accurate and real-time occupancy data, enabling precise control of energy-consuming devices. The scalability and adaptability of the proposed IoT-based energy management system make it suitable for various settings and organizational needs. It offers organizations the opportunity to create sustainable and energy-efficient environments, reducing their carbon footprint and contributing to a greener future. Additionally, research can investigate the potential integration of renewable energy sources, demand response mechanisms, and smart grid technologies to further enhance energy efficiency and sustainability. Overall, the integration of IoT technologies with the bidirectional visitor counter technique offers a promising solution for organizations seeking efficient energy management practices. By implementing this system, organizations can achieve significant energy savings, reduce operational costs, enhance occupant comfort, and contribute to a sustainable future. In conclusion, the research demonstrates the potential of IoT-based energy management using the bidirectional visitor counter technique as a viable solution for optimizing energy consumption and promoting sustainability. Future research and advancements in this area hold the promise of further improving the accuracy and effectiveness of energy management systems, leading to even greater energy efficiency and environmental impact reduction.

10. Acknowledgment

support, and constructive feedback throughout the project. We also thank the faculty and staff of [Department/Institution Name] for their continuous support and encouragement. We are grateful to the anonymous reviewers whose valuable comments and suggestions helped us improve the quality of this paper. Finally, we thank our families and friends for their unwavering support and encouragement throughout our academic journey.

Appendix

Appendix A: Data Collection Methodology In this study, data regarding the implementation of the IoT-based energy management system using the bidirectional visitor counter technique were collected through a combination of observational methods and data logging. The collected data included timestamps and the direction of movement. Occupancy Data Logging: The collected data from the sensors were logged in a central database or cloud storage system. The database recorded the occupancy status at each time interval based on the visitor count and direction of movement. Data Analysis: The collected occupancy and energy consumption data were analyzed to evaluate the effectiveness of the IoT-based energy management system.

86 Online shopping using Javascript

V. Ganeshkumar[1,a] and N. Kanagaraj[2]

[1]Student, Department of Computer Science, Karpagam Academy of Higher Education, Coimbatore, India
[2]Assistant Professor, Department of Computer Science, Karpagam Academy of Higher Education, Coimbatore, India

Abstract: In recent years, the popularity of online shopping has soared, offering customers a convenient and accessible way to shop for their desired products. Technological advancements have greatly improved the user-friendliness of internet shopping, allowing customers to effortlessly explore various online businesses and make purchases at their convenience. JavaScript, a widely utilized programming language, plays a crucial role in website development, enabling the creation of dynamic and interactive web pages. By leveraging the power of JavaScript, our online store provides a seamless browsing experience, allowing users to explore a wide range of products, access detailed information, add items to their carts, and proceed with secure transactions. We have dedicated our efforts to designing a user-friendly website that enhances the overall shopping experience.

Keywords: Shopping in online, e-commerce, e-Shopping, online site, purchase

1. Introduction

E-commerce, also known as online shopping, has witnessed a significant surge in popularity, revolutionizing the way business is conducted. It encompasses buying and selling products and services through websites or mobile applications. The convenience of browsing a vast array of items, comparing prices, and making purchases from the comfort of one's home has fundamentally transformed the shopping experience.

As online shopping gains traction, businesses are increasingly focusing on enhancing their online presence to attract more customers and drive sales. The internet has provided small businesses and entrepreneurs with global opportunities, opening up new prospects through online purchases.

The development of e-commerce websites has become crucial in this context. These platforms serve as a medium for companies to showcase their products and services, while enabling customers to explore and make purchases. Building such websites requires various technologies and programming languages like HTML, CSS, JavaScript, and server-side scripting languages.

This project aims to develop an online store using JavaScript as the primary focus. We will explore the advantages of utilizing JavaScript in web development and leverage its numerous features and functionalities to enhance the online shopping experience.

The Indian e-commerce market is rapidly expanding due to several factors. The increasing number of internet users, widespread adoption of smartphones and mobile internet, and the convenience offered by online shopping have contributed to its growth. Additionally, the COVID-19 [1] pandemic has accelerated the adoption of e-commerce in India, as people prefer to shop online to maintain social distance and avoid face-to-face interactions. The surge in digital payment methods during the pandemic has further bolstered the expansion of India's e-commerce market.

While major players like Flipkart, Amazon India, and Snapdeal dominate the Indian e-commerce landscape, there are also numerous smaller players and niche platforms targeting specific product categories or geographical areas. This rising demand for online shopping in India presents ample opportunities for businesses to enter the e-commerce market and expand their reach to a larger audience.

2. Advantages of Online Shopping

Online shopping offers several advantages over traditional brick-and-mortar shopping. Some of the key benefits include [2]:

1. Convenience: One of the primary advantages of online shopping is convenience. You can shop from anywhere, at any time, without the need to physically visit a store. This saves time and effort.
2. Wide range of products: Online shopping provides access to a vast variety of goods and services

compared to traditional shopping. You can browse items from multiple sellers and brands, compare prices, and choose the one that best fits your requirements.

3. 24/7 availability: Online stores are open 24/7, including weekends and holidays, allowing you to shop at your convenience.

4. Cost savings: Online shopping can be more cost-effective as you can compare prices from different sellers and take advantage of sales, discounts, and promotional offers.

5. Easy payment options: Online shopping offers a range of convenient payment options, including credit/debit cards, digital wallets, and net banking, simplifying the purchase process.

6. Doorstep delivery: Online shopping websites provide doorstep delivery, eliminating the need to physically pick up items from a store. This saves time and effort.

7. Reviews and ratings: Customers can review and rate products on online shopping platforms, helping you make informed decisions based on the experiences of previous buyers.

Overall, online shopping offers numerous benefits over traditional shopping, making it a preferred choice for customers worldwide.

3. Why One Should Buy From Online-Site?

Personal preferences and individual needs play a significant role in determining what products are chosen for online shopping. However, certain items are commonly purchased online due to their convenience and availability. Here are some examples:

1. Electronics: Products like computers, smartphones, and gaming consoles are frequently bought online due to their affordability and the convenience of home delivery.

2. Clothing and Accessories: Online shopping has gained popularity for apparel and accessories, as it allows for easy browsing through a wide range of products from various brands, with the added benefit of doorstep delivery. Many online stores also offer free returns or exchanges, making it simpler to find the right fit.

3. Beauty and Personal Care Products: Online shopping for beauty and personal care items is practical because it provides access to a diverse selection of products from different brands. Customers can compare prices, read reviews, and make informed purchases.

4. Books: Online book buying is common as it provides access to a vast collection of books, including rare or out-of-print editions. The convenience of having books delivered to your doorstep is a significant advantage.

5. Groceries: Online grocery shopping has gained popularity, particularly during the COVID-19 pandemic, due to the convenience of doorstep delivery. Customers can easily order essential items without leaving their homes.

Ultimately, the choice of what to buy online depends on individual preferences and needs. Online shopping is a popular option worldwide because it offers comfort, accessibility, and a wide variety of products to choose from.

4. Why One Should Avoid Purchasing Online?

While online shopping offers numerous advantages, there are certain items that should be approached with caution. Here are some examples:

1. Prescription medication: It is not recommended to purchase prescription drugs online as they may be unsafe or counterfeit. It is crucial to obtain medications from reputable pharmacies with a valid doctor's prescription.

2. Perishable items: Fresh produce, meat, and dairy products are examples of perishable items that may not be suitable for online purchasing. These items can degrade during transportation or have a shorter shelf life, compromising their quality.

3. Large furniture items: Buying large furniture pieces such as sofas or beds online can be challenging since it is difficult to judge their size, comfort, and quality without physically seeing or trying them out.

4. Expensive jewelry: While online jewelry shopping can be convenient, there is a risk of fraud or receiving counterfeit goods. It may not be the best choice for purchasing expensive or valuable jewelry items.

5. Cars or other vehicles: It is not advisable to purchase a car or any other vehicle online since it is important to physically inspect and test-drive the vehicle before making such a significant investment.

What to avoid buying online ultimately depends on individual requirements and preferences. It is essential to exercise caution and conduct thorough research before making any online purchase, especially for expensive or delicate items.

5. Things to Keep in Mind Before Making an Online Purchase

To ensure a secure and successful transaction, here are some tips to consider before making an online purchase:

1. Shop from reputable websites: Stick to well-known and reliable websites with a proven track record of safe and secure online transactions.
2. Check for secure connections: Ensure that the website has a secure connection (indicated by the padlock icon in the browser address bar) before entering sensitive information like credit card details.
3. Read product reviews: Take the time to read reviews and ratings from other customers to gauge the quality and reliability of the products you are considering.
4. Compare prices: Compare prices across different websites to ensure you are getting the best possible deal.
5. Check the return policy: Review the website's return policy to ensure you can return or exchange the item if needed.
6. Avoid public Wi-Fi: Refrain from making online purchases using public Wi-Fi networks, as they may not be secure and can put your personal data at risk.
7. Keep records: Make a note of your purchase, including the order number or confirmation email, for future reference.
8. Use strong passwords: Create unique and secure passwords for each online account to avoid using the same password across multiple websites.

By keeping these tips in mind, you can make secure and successful online purchases.

5.1. *Definition of consumer preference*

Consumer preference [3] refers to the subjective evaluation and comparison of various goods or services by customers based on their unique preferences, requirements, and desires. It encompasses the decisions individuals or groups of consumers make when presented with different options and their ranking of those options in relation to one another. Consumer preference can be influenced by factors such as quality, price, availability, brand, reputation, and personal experiences. To effectively cater to the demands and expectations of target customers, businesses must have a deep understanding of consumer preferences.

5.2. *What is consumer preference?*

Consumer preference refers to the decision-making and choices made by individuals or groups of consumers when presented with options for goods or services.

It involves the subjective evaluation and comparison of different possibilities based on individual preferences, requirements, and desires. Factors such as quality, price, brand, reputation, availability, and personal experiences can influence consumer preference. To create effective marketing strategies, customize products or services to meet the needs and desires of target customers, and maintain competitiveness in the market, businesses need a comprehensive understanding of consumer preferences.

5.3. *Online customers*

Customers can be individuals, companies, or other entities that purchase products or services from sellers, suppliers, or providers. Customers are vital to the success of any business as they generate the revenue necessary to sustain it. They can be categorized in various ways, such as end users or B2C (business-to-consumer) [4] customers who purchase goods or services for personal use, or business clients or B2B (business-to-business) customers who buy on behalf of their company or institution. Customers can also be classified based on their purchasing frequency, such as one-time, repeat, or loyal customers. Establishing a strong customer base is crucial for business success as it increases sales, fosters brand loyalty, and enhances customer satisfaction.

6. Dos and Don'ts in Online Shopping

Here are some dos and don'ts to consider when engaging in online shopping:

Dos:

1. Compare prices on different websites to get the best deal.
2. Check product reviews written by previous buyers to gauge product quality.
3. Review shipping and return policies before making a purchase.
4. Always use a credit card or secure payment channel for online transactions.
5. Keep a record of your orders and shipping information.
6. Look for deals and coupons before making a purchase.
7. Ensure the website is secure and has a valid SSL certificate before entering personal information.
8. Carefully review sizing charts and product descriptions to ensure you get the correct size and product.

Don'ts:

1. Avoid making purchases from unreliable or unknown websites.

2. Never disclose personal information, such as your social security number, on any online retailer website.
3. Avoid clicking on links in phishing emails promising inflated discounts or promotions.
4. Refrain from impulsive purchases and thoroughly review product descriptions and customer reviews.
5. Pay attention to shipping and return guidelines.
6. Avoid using public computers or Wi-Fi for online shopping as they may not be secure.
7. Do not save your credit card information on any website as it may compromise your security.
8. Remain vigilant for any fraudulent activities by regularly checking your bank statements.

7. A Few Online Services Include

Here are some popular online services:

1. E-commerce websites: Online stores that allow you to order products for delivery to your doorstep. [5]
2. Online banking: Access and manage your bank account online, including money transfers, bill payments, and balance checks.
3. Social media: Platforms like Facebook, Twitter, and Instagram that enable users to interact, share content, and communicate online.
4. Email: Services like Gmail, Outlook, and Yahoo that allow users to send and receive electronic messages.
5. Online education: Websites like Coursera and Udemy offer online courses and tutorials on various subjects.
6. Cloud storage: Services like Dropbox, Google Drive, and OneDrive that allow users to store and access data online from any device.
7. Video streaming: Online services like Netflix, Hulu, and Amazon Prime that provide access to movies, TV shows, and other video content.
8. Online travel booking: Websites like Expedia and Booking.com where users can make online reservations for flights, accommodations, and rental cars.
9. Online food delivery: Services like Uber Eats, DoorDash, and Grubhub that enable users to order food from local restaurants and have it delivered to their doorstep.
10. Online gaming: Platforms like Steam and Epic Games that allow users to purchase and play video games online.

8. Review of Literature

Extensive research has been conducted to understand consumer behavior in the context of online shopping.

Here is a brief summary of some key findings from the literature on online shopping:

1. Consumer Attitudes: Several studies indicate that consumer attitudes towards online shopping are generally positive, driven by factors such as convenience, cost, and product variety.
2. Product Reviews: Online product reviews play a significant role in consumer decision-making. Positive reviews tend to increase the likelihood of purchasing a product, while negative reviews can deter potential buyers.
3. Trust and Security: Trust and security are major concerns for online shoppers. Consumers are more likely to trust online merchants with secure websites, clear return policies, and transparent business practices.
4. Gender Differences: Studies suggest that gender disparities exist in online shopping behavior. For example, men may be more inclined to shop online for electronics and gadgets, while women may be more focused on clothing and beauty products.
5. Impulse Buying: Online shopping is conducive to impulse purchases. Factors such as limited-time offers, free shipping, and discount coupons have been found to trigger impulsive buying behavior.
6. Mobile Shopping: The increasing use of smartphones has led to a rise in mobile shopping. Consumers are more likely to make purchases on their mobile devices when the transaction process is quick, easy, and convenient.

Overall, research indicates that customers hold positive attitudes towards online shopping. However, important influences on consumer behavior include trust, security, and the impact of product reviews.

9. Statement of the Problem

Consumer security [6] and trust are significant issues in online shopping. Customers often express concerns about the security of their personal and financial information when making online purchases. Reports of online fraud and data breaches have contributed to a decrease in customer trust in online commerce.

Another challenge associated with online shopping is the inability to physically inspect products before purchasing. Customers may be uncertain about the quality, size, or appearance of a product if it is not adequately represented in online photographs or descriptions. This can lead to dissatisfaction and the need for returns or exchanges, which can be inconvenient for both the customer and the retailer.

Delivery times and logistics present another issue. Customers expect prompt and efficient delivery of

their products, but the timing can vary greatly depending on the retailer, region, and shipping method. Late or delayed deliveries can result in customer dissatisfaction and requests for refunds or cancellations.

Overall, the main challenges in online shopping are consumer security and trust, the inability to physically inspect products, and delivery effectiveness and timing.

10. Scope of the Study

The study will focus on the following areas:

1. Consumer behavior: Understanding consumer attitudes, motivations, and behaviors when shopping online, as well as the factors influencing their decision-making.
2. E-commerce platforms and technologies: Examining the features, functionality, and user experience of e-commerce platforms used for online shopping.
3. Online security and privacy: Investigating the control consumers have over their personal data, as well as the security measures and protocols employed by online retailers to safeguard customer information.
4. Logistics and delivery: Analyzing the logistics and delivery process to ensure prompt and effective delivery of goods to customers, considering factors that affect delivery timing and effectiveness.
5. Online reviews and ratings: Exploring the impact of online product ratings and reviews on consumer choice, as well as the implications of fabricated or manipulated reviews on consumer trust.
6. Online marketing and advertising: Investigating the strategies and tactics used by online retailers to attract and retain customers, and evaluating the effectiveness of these measures.

11. Results and Discussion

The study will employ the Garret's Ranking Technique to examine consumer preferences in online shopping.

Consumer preference-based distribution refers to the distribution of goods and services according to consumer demand in a particular area or region. For instance, if there is a significant demand for organic food products in a specific area, consumer preference-based distribution would ensure that online vendors have a good selection of organic food items available for delivery to that region. This may also involve stocking up on organic food items in local shops or supermarkets to meet consumer demand.

By understanding and catering to consumer preferences, businesses can effectively meet customer needs and desires, leading to increased customer satisfaction and loyalty.

11.1. Implications of policy

The implications of internet shopping for policy can include:

1. E-commerce regulations: Policymakers may consider implementing regulations that govern the operation and management of e-commerce platforms. These regulations may cover areas such as data privacy, cybersecurity, consumer protection, dispute resolution, taxation, and competition.
2. Digital infrastructure: Policymakers may prioritize investments in digital infrastructure, including broadband networks, data centers, and mobile networks, to ensure reliable and secure online shopping experiences. Initiatives to improve internet access, reliability, speed, and address issues like the digital divide and net neutrality could fall under this category.
3. Consumer education: Policymakers may consider funding consumer education programs to empower individuals to become informed and savvy online shoppers. These programs could cover topics such as safe online practices, fraud prevention, conflict resolution, and online consumer rights and responsibilities.
4. International cooperation: Policymakers may explore collaborations with international organizations and other countries to establish uniform standards and best practices for online commerce. Initiatives to harmonize laws, establish cybersecurity protocols, and promote international trade could be part of this category.

Table 86.1. Wise distribution of respondents based on consumer preference

S.No	Preference	Garret's mean score	Rank
1.	Groceries	36.84	XI
2.	Fast food	33.78	XII
3.	Cosmetics	39.42	X
4.	Books	66.02	I
5.	CDs/DVDs	56.02	IV
6.	Toys	46.28	VII
7.	Furniture	44.12	VIII
8.	Clothes	53.72	VI
9.	Electronic Goods	54.92	V
10.	Movie Ticket	59.3	III
11.	Airplane Ticket	66	II
12.	Jewellery	41.58	IX

Source: Primary data.

To effectively address the potentials and challenges presented by the rapidly evolving field of online shopping, governments, industries, and civil society need to coordinate and collaborate in tackling the complex and multifaceted policy implications.

12. Conclusion

In conclusion, online shopping has gained popularity among consumers as a convenient method of purchasing goods and services. With the growth of e-commerce platforms, consumers now have access to a wide range of products from around the world, often at affordable prices.

However, online shopping also brings challenges and concerns such as fraud, data security and privacy, and product quality and authenticity. Therefore, it is crucial for decision-makers, businesses, and civil society to work together to address these issues and ensure a secure environment for online shoppers.

With effective policy interventions in areas such as e-commerce regulations, digital infrastructure, consumer education, and international cooperation, online shopping can continue to provide benefits for both consumers and businesses.

The future of online commerce will depend on the success of regulators and stakeholders in navigating these opportunities and challenges, ensuring that the advantages of this innovative and dynamic industry are accessible to all.

Abstract: The major goal was to build a social platform application by breaking down the crucial components of the renowned MERN stack. The MongoDB, Express, React, and Node.js (MERN) stack allows programmers to unify web development under the JavaScript umbrella. After several months of research, a successful, completely functional application was created. With the program's present functionality set, Aeal can use it as both a platform for connecting individuals and a work management tool.

Keywords: MongoDB, express, node, react, JavaScript

1. Introduction

There is a greater need than ever for full-stack developers. According to a survey by Indeed, the highest-demanding position has an impressive average compensation in the US of $110,770 [1]. Someone who is technically capable of working on both the front-end and back-end development of dynamic websites or online apps is known as a full-stack developer. The LAMP stack, which consists of Linux, Apache, MySQL, PHP or Perl, and Java (Java EE, spring), which contains a number of computer languages, was previously the main framework for online development. With the advent of the MERN stack, JavaScript simplifies web development by providing both client-side and server-side capabilities. The stack's four main building blocks are MongoDB, Express.js, React.js, and Node.js.

2. Literature Review

We have a number of apps for chatting and video calling with friends as well as platforms like Instagram, Face book and LinkedIn where we can get updates on various topics like entertainment, news, sports and more. Some apps are specially designed for sharing entertainment related activities or activities etc. like Instagram, Face book, LinkedIn to know news about many things including entertainment, news, sports.

The social media platforms that are available now are: Face book: Face book was first released in 2004 as the Harvard online social networking website, accelerated to different universities and eventually reached out to all of us. In 2009, it became the largest social media site. It remains a great photo sharing site.

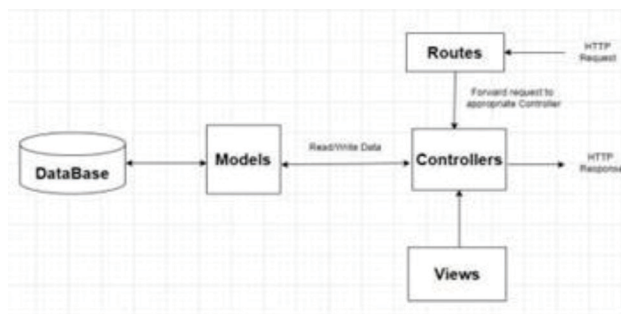
Marketing strategies have found Face book to be useful because it encompasses a wide range of personal and organizational interests. Twitter: Twitter was founded in 2006 by means of Odeon, Inc, and for Odeon Inc employees and family individuals, it changed to be the simplest in the beginning. It became a public network in 2006. Twitter provides a real-time web service that allows users to send short messages to different customers and comment on other people's posts. A Tweet is a small message of a maximum of one hundred and forty characters that users create to speak their mind.

The problem we are trying to solve is the lack of a platform for developers where they can get all the services like asking for a code bug, sharing code snippets, working on the code editor online with different developers in real time, creating new connections, and sharing your experiences on the social platform—all in one place. There are several alternatives but the difference is that Jiphy provides all the features like social media platform, code editor and compiler, social forum, blog post and QandA section in a single platform.

When a user signs up for Jiphy, they will experience a clean user interface, an FAQ section on how the site works, and a few blog posts to get them started on our site. People can use it as a platform to increase the number of connections, or they can also use it to work on the same code base in real time with multiple developers. We used the MERN stack in web development and firebase for authentication. We have also integrated a machine learning model into our code compiler to help with automatic compilation. Everything is hosted as a separate microservice. The web part is containerized and hosted on Heroku, and the machine learning model is hosted on AWS SagaMaker. The future scope of our project would be to open source and ask other developers for their input and new ideas, a few of them will be a technical news update section and a chatbot tutorial section to answer your technical questions.

3. Methodology

MongoDB, Express, React, and Node make up the acronym MERN. Express.js is a web server framework, Node.js is the server-side platform for MongoDB, a database, and React.js is a library for web shopping. Four cutting-edge technologies are being used throughout MERN's development process, from the front end to the back end. Contractors don't have to spend time or effort learning new technology to increase productivity. Using the same JavaScript platform, programmers may increase software scalability and maintain software products because the stack is backed by a sizable number of open source packages and a robust community. The Node.js server-side technology, which powers the MERN in Figure 87.1, offers extraordinarily high speed and lightning-fast responsiveness for all activities, even managing large and complex amounts of data.

A large group of people promote Express.js, an open-source framework that is utilized in business applications. Therefore, developers can confidently use this framework for their modest to large-scale


applications. Express.js comes with a number of support packages and other developer features to help you build a better system. However, this doesn't slow down Node.js. The widely used Node.js forum of today makes extensive use of Express.js. MongoDB Inc. founded the firm in October 2007. Similar to Windows Azure and Google AppEngine, it was a PaaS (Platform as a Service) solution. Later in 2009, it was made open source. A text-based, NoSQL-based website is MongoDB. MongoDB often avoids database formats like JSON, which has a very flexible schema called BSON, in order to be compatible with all document types. Benefits and Drawbacks of MongoDB The following are some of MongoDB's most alluring qualities that have persuaded current users to use it: Each collection has its own size and number of documents because MongoDB stores data in the JSON format.

However, they are very adaptive when it comes to archiving. In contrast to RDBMS, after users install, uninstall, or update MongoDB, they won't have to spend much time establishing if the requirements are met or not because MongoDB data is often not linked to one another and doesn't offer join queries. MongoDB can be scaled easily. A "collection" in MongoDB is a group of nodes that have shared data. By adding a new node to the cluster, users can swiftly extend the system. Because the distinct identity_id is always determined automatically, queries are always in Figure 87.2.

Executed swiftly: Data requests will be cached in RAM, reducing the number of times they must reach the hard drive and enabling faster reads and writes. Moreover, numerous processes will be used to commit to a social platform: back-end creation, front-end creation, and eventually operation testing. Due to labour constraints, it is not advised to go into great detail about every project component. However, it may show each step needed to run the MERN program correctly. The application endpoint is made using the Express.js library, which utilizes Node.js as its foundation. In order to connect to the MongoDB website and store data in JSON format, the Mongoose library

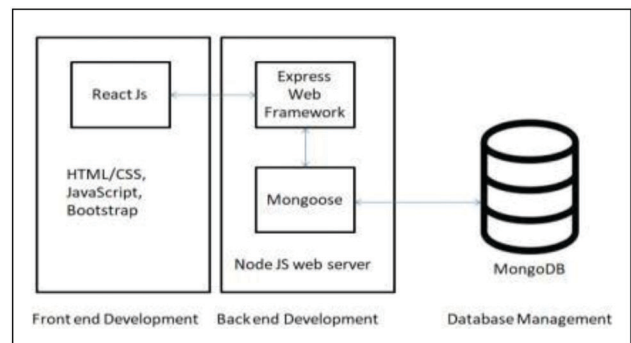
Figure 87.1. Architecture of MERN.
Source: Author.


Figure 87.2. Structure of express JS.
Source: Author.

is also installed. The routing logic is finally put into practice, along with endpoints for interacting with the front-end. To link the MongoDB site to Express. js, the Mongoose node package is installed. An object data modelling tool called Mongoose is used to create MongoDB schemas. Models.

Event Queue: Considered as a repository for storing events (events). An event here can be understood as a specific process in the program. Each event contains information to classify what the event is and accompanying data. Since this is a queue structure, the event queue will operate on a First in First Out (FIFO) basis. This ensures that the order in which events are loaded for processing is the same as the order in which they are placed in the event queue.

The central thread Because it will mark the start and finish of the programming, think of this as the primary thread. The calculation is carried out by the main thread when events are retrieved from the event queue. Additionally, just this single Node application thread is under the program's control. For this reason, a Node program in Figure 87.3 is still referred to as single-threaded. As a result, developers won't have to be concerned about cross-thread concurrency issues like they might on some other platforms like Java.

The division in charge of overseeing IO activities is known as Node API. The IO operation in this case will be managed by a multi-threaded mechanism. Each IO operation also results in the creation of an event, which is then added to the event queue.

4. Experimental Results

The implementation of the social platform will take place in three separate steps:

After developing the front end and back end, the application must then be tested. It is not advised to describe every component of the research in depth due to the work's constrained scope. He might, however, be able to illustrate each step required to construct a MERN application.

4.1. Back-end creation

The Express.js library is used to build the server when developing the application's backend, which is built on top of Node.js. The Mongoose library is then installed to connect to the MongoDB database and store the data in JSON format. Last but not least, routing-related logic is presented because it calls for endpoints to communicate with the frontend.

4.2. Creating a server

In order to compile the JavaScript code on the backend, a server is first required.

Figure 87.3. Event loop mechanism.

Source: Author.

4.3. npm init

Project initialization command.

A new Node.js project is launched using the code previously mentioned. A package.json file is automatically created after the user provides the necessary information regarding the project description and user information. The Express.js framework is used to make use of the already-existing npm packages once the project has been launched, as opposed to the Node.js core HTTP modules, which are used to build the server.

4.4. npm install express

Create an Express.js server command.

Next, a file called app.js is created as an input. All middleware and Node packages are contained in this file.

4.5. Front-end creation

Setting up a React.js application

In the past, configuring and setting up the environment for brand-new React projects was difficult. Setting up Babel to transform JSX into browser-ready code and configuring Web pack to bundle all the application assets were all part of the procedure. Facebook created the "create-react-app" Node.js module as a result of the duration and complexity of this process.

4.6. Setting up route in React.js app

Due to its many unique characteristics, SPA (Single Page Application) is currently recognized as a trend in web app development. The UIs will be generated on a single page when an app is designed using the SPA concept, depending on how the component will be rendered.

Additionally, users can use the URL as a condition to specify which components won't be rendered. The React.js library developed for this function is called React Router. The React.js package React Router is used for standard URL navigation and allows synchronization of the user interface and URLs. Because of the API's straightforward architecture, URL issues may be quickly resolved. You can complete the steps in Listing x by following them.

4.7. Testing the application

The outcome application should now be tested when the back-end, front-end, and connectivity between them have all been properly established. The app functions just like a social platform should, as expected.

5. Conclusion

In order to create a complete end-to-end web application for social networks, this document offers an implementation of the MERN stack and its features. The fundamental concepts, guiding principles, and key methods of each technology are discussed in this article. Also covered are the benefits of such technologies and how to apply them to create a combined backend and frontend application using a NoSQL database engine. Outlining the steps for creating a social media application serves as an example of how the aforementioned ideas might be put to use in a practical situation. All of the project's objectives were achieved, and the results were largely favourable. Later social network usage was developed with the aid of complex implementation approaches. Using the MERN stack, a complete web application for social networking is developed.

88 Erythrosine dye decolorization by sonolysis and its performance evaluation under varying pH conditions of thiazine dye

Mederametla Pragathi[1,a] and Palanisamy Suresh Babu[2]

[1]Research Scholar, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Chennai, India
[2]Project Guide, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract: To investigate the erythrosine dye's decolorization under various pH conditions by sonolysis and analyze its toxic characteristics in wastewater treatment. Materials and methods: The erythrosine dye solution was made with pH 4 and 8 conditions, agitated to perform ultrasonication at the requisite temperatures for 2 hours, and results were taken at their greatest yields. Groups 1 and 2 of each of the six samples were taken for each pH solution in a numerical type of analysis with a confidence interval, G-power of 80%, enrollment ratios all set at one (N=12), and an alpha error level. T-tests were performed using IBM SPSS V 28.0 software to compare the samples. Results: A sonicated erythrosine solution was calculated to be yielding a maximum at 40°C and 70°C for pH 4 and 8 conditions respectively. Sample of independence Between Groups 1 and 2, a T-test was run in the mean-variance with a significance level of 0.001 which is not significant (p<0.05) and results were obtained. In summary: Within the confines of this investigation, it is demonstrated that erythrosine solution can be utilized in the wastewater treatment process by sonicating it to break down its complicated structure under the appropriate conditions.

Keywords: Erythrosine dye, food colorants, advanced oxidation process, wastewater treatment, sonolysis

1. Introduction

The dyes may be difficult to remove and may have adverse effects on the environment, which may complicate wastewater treatment. The benefits of sonolysis include its capacity to generate high removal efficiency for a variety of pollutants and its flexibility to be combined with any effective wastewater treatment procedures to produce even better outcomes three, is a synthetic food dye that is used to add red color to a wide variety of food and beverage products. It is often used in the production of candies, cakes, and other sweets, as well as in the creation of red-colored beverages and other food products. It is a synthetic dye that is made from a combination of chemicals, including iodine and phenyl glycine. It is typically sold in a powder or liquid form and is added to food in small quantities to achieve the desired color. Tablets containing erythrosine are used to treat and prevent infections, including sinus and throat infections [2, 4]. It can be used to make dyes more stable and soluble and provide consistent, homogenous solutions for various uses. It can be utilized in a range of sectors, including textiles, printing, and cosmetics. It is a quick and effective approach to processing dye solutions.

2. Resources and Techniques

The Saveetha Institute of Medical and Technical in this comparative investigation, two distinct sets of samples are utilized: the first set comprises untreated

[a]pinnkymishraa@gmail.com

erythrosine dye solution samples with pH values ranging from 4 to 8, and the second set comprises sonicated erythrosine dye solution samples. The value of G power was determined to be 80% and the coincidence interval of 95% and the sample preparation was given below. A 40 kHz ultrasonic homogenizer was used to start the process of decolorizing the dyes. Readings were taken every 20 minutes during the 2 hours of sonication on the dye solutions with initial concentrations of 100 mg/L and pH ranges of 4, 6, and 8. Electricity in the form of electrical pulses is sent from the generator to the sonicator. During this procedure, cavitation the production and subsequent collapse of microscopic vacuum bubbles occurs. A temperature range of 40 to 70 C was used to observe the procedure. The process was recorded between 30 and 80 C. In order to test the dye solution's absorbance, a sample of the dye solution is placed in a cuvette and placed inside a UV-vis spectrophotometer. Due to the dye's distinctive absorption characteristics, this spectrum can be used to both determine the dye's concentration in the solution and to identify it.

2.1. Analytical statistics

An independent sample t-test and IBM SPSS version 26 were used for the statistical analysis. The sonicated pH 4 and pH 8 solutions were the independent factors; there were no dependent variables. Using the same software [3], a T-test for independent variables with a standard deviation in the standard of mean errors was conducted [3].

3. Results

The obtained results were provided for dye solutions with pH values of 4, and 8, which were discovered to be suitable for azo-dye decolorization. After two hours, the highest decolorization yields, at a frequency of 40 KHz and a concentration of around 100 mg/L, were 95%. Ultrasonic power of 100w was included.

3.1. Effect of pH

The pH 4, and 8 samples are subjected to sonication. Phosphoric acid and sodium hydroxide were used to attain pH balance. With the pH 4 solution, the most solubility was observed. In terms of time and temperature, more sonication is needed to dissolve the particles in the sample with a pH of 8.

3.2. Effect of time

The maximum amount of breaking down of particles was observed at 80 min for pH 4 conditions which are represented in Table 88.1 with respect to other degrading durations. As the pace of reaction steadily increases with time, it has been discovered through tests that the

Source: Author.

impact of time on the rate of degradation is significant. Table 88.3 shows the mean, standard deviation, and standard error mean of the pH 4 and 8 solutions at standard intervals for the T test group statistics, whereas Tables 88.4 and 88.5 provide the findings of the independent sample tests.

3.3. Effect of agitation

According to a research, erythrosine was adsorbed on a copper-coordinated dithiooxamide metal-organic framework (Cu-DTO MOF) [3, 10] at similar agitation speeds (>180 rpm), with superior outcomes at only a specific rpm. In this study's aspect, stirring rates of 150, and 250 rpm were used in succession for the pH ranges under consideration at room temperature.

3.4. Effect of temperature

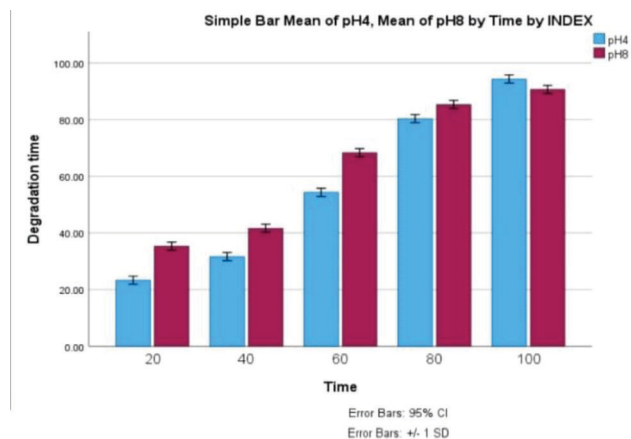
Table 88.2 compares and analyzes the impact of temperature on dye solutions. At 40°C, the pH 4 solution had the highest solubility percentage and was nearly


Figure 88.1. Comparison of mean amount of degradation at regular intervals of time on X-axis and Y-axis with temperatures of pH 4 solution CI: 95%; SD +/-1.

Source: Author.
Figure 88.2. Comparison of mean amount of degradation of tartrazine dye solutions on X-axis and Y-axis with different temperatures CI: 95%; SD +/-1.

stable, despite the temperature increase, pH 8 at 70°C. Table 88.6 shows the mean, standard deviation, and standard error mean of pH 4 and pH 8 solutions at sonicated temperatures for the T test group statistics, whereas Tables 88.7 and 88.8 are the independent sample test results Figure 88.1–88.3 [17].

Additionally, an ultraviolet-visible spectrophotometer with a photoelectric detector is used to measure the sample solutions' absorbance at a maximum absorption wavelength of 590 nm.

4. Discussion

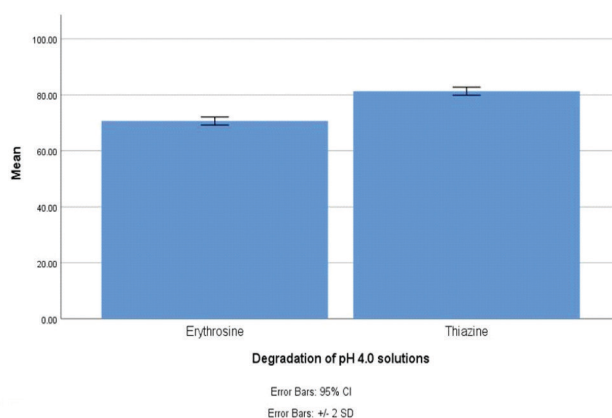
The ultrasonic decolorization increased with decreasing initial concentration of dyes, and the ultrasonic decolorization rate increased moderately with


Figure 88.3. Comparison of pH 4 solutions of Erythrosine dye and thiazine dye while X-axis with time and Y-axis with degradation rate CI: 95%; SD +/-2.

Source: Author.

increasing treatment time for all of the dye solutions, according to the observed results, which were given for pH 4, and 8 dye solutions, which were found to be suitable for decolorizing the azo dye. The results for the mean, standard deviation, and standard error mean for the time and temperature of the sonicated pH 4 and 8 solutions are included in Tables 88.3 and 88.6 of the T-test group statistics. Levene's test for equality of variance and the t-test for equality of means are used in Tables 88.4 and 88.7 to demonstrate the independent sample test for the assumed variance mean of pH 4 and 8 solutions. Table 88.8 shows the standardizers, point estimates, 95% confidence intervals, and temperature and time impact sizes for independent samples. The particular contaminants found in the wastewater, along with other elements like the amount of water to be treated and any applicable discharge restrictions, will determine which approach is best. At pH 4, the average rate of chemical breakdown of erythrosine is compared throughout time. However, when sonication occurs, the degradation rate also rises and the degradation percentage slowly increases. The usual disintegration rate throughout time and pH ranges are contrasted in Figure 88.3. The physicochemical properties of a substance can change depending on its pH level, which in turn impacts how rapidly a substance breaks down when subjected to ultrasonication. Future scope: Additionally, there have been concerns about the potential effects of erythrosine on human health, including allergies, hyperactivity, and thyroid dysfunction.

5. Conclusion

The study was conducted using an ultrasonicator to discolor the chosen food color. The obtained outcomes

demonstrated that, under ideal conditions, decolorization is more promising at pH 4 than at neutral and higher pH levels like 6 and 8Individuality-exemplar Results were obtained via a T-test that was conducted between Groups 1 and 2 in the mean-variance under a significance threshold of 0.001 with a significant ($p<0.05$) effect. It was explained how hazardous erythrosine is and how it affects water bodies. However, depending on the unique characteristics of the dye, the precise parameters necessary for this to happen, such as the frequency and intensity of the sound waves and the length of the sonolysis treatment, would vary. Any potential adverse effects or sonolysis process byproducts would also need to be considered.

89 Synthesis and characterization of silver nanoparticles using listed novel essential oils for its anti-inflammatory efficiency in comparison with Diclofenac drug

Siva Manish Kumar[1,a] and Palanisamy Suresh Babu[2]

[1]Research Scholar, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Chennai, India
[2]Project Guide, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract: The new essential oils of Thymus vulgaris L., Chamomilla, Eucalyptus globulus L., and Cinnamomum camphora were compared with the medication Diclofenac to create the reducing agents needed to create silver nanoparticles. Materials and Methods: Gas chromatography mass spectrometry had found aromatic hydrocarbons, alkenes, ketones, alkaloids, and other compounds in novel essential oils from the previous study. UV-Visible and Fourier transform infrared spectroscopy, on the other hand, revealed the chemical groups and surface resonance features of the samples, the confidence level was 95%, and the G power was 80%. Results: Field emission scanning electron microscopy shows that the silver nanoparticles in the sample that had been made by mixing novel essential oils form nanoscale spheres with a mean diameter of 12 to 39 nm and the With a p-value of 0. Two groups and four samples were used in the test. Silver nanoparticles had a remarkable ability to prevent bovine serum albumin protein denaturation, with the greatest inhibition, in their anti-inflammatory activity. The generated particles were biofunctionalized with organic molecules and had a crystalline, spherical shape. The produced silver nanoparticles have a considerable anti-inflammatory potential and could be a possible source of the anti-inflammatory medication because they greatly reduced protein denaturation. From the in vitro anti-inflammatory activity, the highest inhibitions were observed at 200 g/mL and 250 g/mL compared to diclofenac-drug the P value was found to be less than 0.05. Conclusion: As a result, eco-friendly silver nanoparticles made using a blend of unique essential oils can be considered an alternative method for producing this nanomaterial with high anti-inflammatory and stability.

Keywords: Essential oils, thymus vulgaris L, chamomilla, eucalyptus globulus L, cinnamomum camphora, fourier transform infrared spectroscopy, clean technologies, UV-VIS, anti-inflammatory activity

1. Introduction

Nanotechnology was a rapidly expanding field in which nanoscale materials with various forms, distributions, and application potentials were introduced creating and synthesizing materials at the nanoscale was the focus of nanotechnology. Although conventional physical and chemical preparation methods produce nanomaterials successfully, they typically cost a lot, take a long time and could be harmful to the environment. Regarding the applications of metal nanoparticles, it was therefore novel essential to continuously search for environmentally friendly and cost-effective methods. In addition to being a simple and cost-effective method, the synthesis of metal nanoparticles by using plants involves biomolecules that lower the risk of toxicity to humans and ecosystems. The biomedical community was becoming more and more interested in medicinal plants because of their many compounds, which include anti-inflammatory, antibacterial, antiviral, and antitumoral properties. Silver nanoparticles were the most significant of all nanoparticles because, low concentrations, they do not pose a threat to human health and possess anti-inflammatory properties More than 560

publications in the Pubmed database and more than 1450 in the Science Direct databases have addressed the synthesis and characterisation of anti-inflammatory silver nanoparticles employing new essential oils during the past two years. It was well known that the oxidative stress caused by the inflammatory response can promote diabetes and insulin resistance, aid in the growth of tumors, increase the risk of atherosclerosis, coronary heart disease, and Alzheimer's disease lesions [17]. The search for alternative substances that were homeostatic, modulatory, effective, well-tolerated by the body, and capable of relieving inflammation is also important due to the numerous and severe side effects of these medications. However, the majority of these active ingredients were insoluble, which reduces their bioavailability, increases their clearance from the body, and increases their administration throughout the body. A few of the numerous advantages offered by nanosized drug delivery systems are their solubility, bioavailability, improvement of pharmacological activity, protection from toxicity, prolonged distribution, and resistance to both physical and chemical degradation. And with that, a new era of herbal research began.

2. Materials and Methods

2.1. Extraction of essential oils

Among the clean methods used to extract new essential oils from plants is the steam distillation process. The essential oil fractions were obtained using a separating funnel after three hours of mixing 100 g of plant materials with 1000 mL of distilled watered G power was 80% and the confidence level was 95%. The extracted essential oils from different plants were divided into separate 10 mL vials and kept at room temperature for in vitro anti-inflammatory activity and characterisation tests (Majda elyemni et al., 2019) as shown in Table 89.1.

2.2. Analysis of essential oils using GC-MS

A 0. 25-micron film (30 m/0. 25 m internal diameter) was used in conjunction with the Agilent GC 7890a/MS5975c gas chromatography mass spectrometer (column length: db5 ms from Agilent) to ascertain the volatile chemical makeup of the essential oil mixture. Noble gas helium was utilized as the carrier gas, with a flow rate of 1 mL per minute and an oven temperature gradient of 5°C per minute set at 250°C. The essential oil mixture's similar compounds was identified by comparing the GC-MS scan spectra to the NIST library and the G power was 80% [3].

2.3. Silver nanoparticles synthesis

With minor modifications, silver nanoparticles was synthesized used a well-established method [3, 17]. Ten milliliters of a freshly made blend of unique essential oils were added to fifty milliliters of 1 mm silver nitrate aqueous solution in order to initiate the silver nitrate bio-reduction process to silver nanoparticles. The combination was incubated at room temperature in the dark until its color changed in order to stop silver nitrate from becoming photoactivated under static conditions. As the hue changed, silver nanoparticles developed. The mixture was washed twice with distilled watered after being centrifuged for 15 min at 3500 rpm. For characterization and anti-inflammatory activity as it was a type of clean technologies, the recovered pellets from centrifugation was placed in a petri dish and, using a kind of hot plate, dried for two hours at 50°C as shown in Table 89.2.

According to [22], using a UV-visible spectrophotometer (UV-3600 PLUS, Shimadzu Corporation, Tokyo, Japan), the UV-Visible spectrum of the reaction mixture was measured to track the silver ion reduction which was a type of clean technologies. The blank was distilled water.

2.4. Anti-inflammatory activity

A 5 mL reaction mixture containing 0.2 m of bovine serum albumin (BSA), 2.8 mL of phosphate buffer (pH 6. 4), and 2 mL of silver nanoparticles at different concentrations (50, 100, 150, 200, and 250 μg/mL) was incubated for 15 minutes at 37°C. After that, the mixture was heated to 90°C for five minutes. The same amount of distilled watered served as the controlled. Utilizing the vehicle as a blank, their absorbance was measured at 650 nm following cooling. Diclofenac, a commercial drug, was used as a reference drug at concentrations for the purpose of determining absorbance of 50, 100, 150, 200, and 250 μg/mL [1] as shown in The percentage of inhibition of protein denaturation was computed and is shown in Table 89.3 where at was the test sample's absorbance and ac was the controlled absorbance. Plotting percentage inhibition in relation to treatment and controlled substance concentrations allowed for the calculation of the drug concentration for 50% inhibition. (effective concentration).

2.5. Statistical analysis

SPSS version 21 was used to statistically analyze all of the data. An independent sample t-test was used to check for normalcy in the anti-inflammatory activity measured using silver nanoparticles synthesized from novel essential oils blend and diclofenac medication. The dependent variables were essential oil blend concentration and essential oil blend percentage denaturation inhibition, while the independent variable was absorbance. The variations in anti-inflammatory activity were deemed significant at the 0.05 level.

The t-value was 16.21. The p-value was 0.009736. The result was not significant at p < 0.05.

3. Results

3.1. Silver nanoparticles synthesis

Silver nanoparticle synthesis was the primary focus of modern nanotechnology. Currently, plant extracts were utilized for the biosynthesis of nanoparticles which was one of the clean technologies. The development of experimental biologically based nanoparticle synthesis processes was an essential subfield of nanotechnology

as shown in Figure 89.1. The employment of a combination of aqueous Ag+ ions and essential oils to produce silver nanoparticles is the main emphasis of our work, as illustrated in Figure 89.1. Compared to a number of conventional methods for combining silver nanoparticles, this one appears to be less expensive.

3.2. Essential oil GC-MS analysis

(4%), Bicyclo[2.2.1]heptan-2-one (4.09%), Thymol (17.39%), Eugenol (0.5%), Caryophyllene (1%). The results also showed that thymol (17.39%) was the most dominant compound and it had been mentioned in Figure 89.2.

3.3. UV-VIS analysis

Based on the peaks in optical absorbance, UV-visible spectroscopy was utilized to detect and validate the existence of silver nanoparticles. By recording the absorption spectra of the produced silver nanoparticles against water, the production and stability of the particles were observed. Figure 89.3 depicts silver nanoparticle UV-Visible spectra produced by 10 mL of essential oils with 50 mL of AgNO$_3$ 10^3 mol/L. The surface plasmon resonance, or characteristic peak of silver nanoparticles, increased with incubation time and was located between 300 and 350 nm. Nanoparticle nucleation, increasing size, and gradual reduction were all evident in the UV-Visible spectra thanks to the increasing absorbance bands [16]. The production

and stability of the produced silver nanoparticles were observed using their absorption spectra against water [12, 16]. Initially, visual observation was used to record the metallic black change of the mixture solution, which consisted of a mixture of essential oils and 1 mM silver nitrate solution. The production of silver nanoparticles was shown by the creation of plasmons at the colloid surface, which resulted in a color shift following incubation, as shown in Figure 89.3.

4. Discussion

The present study demonstrated that the combination of novel essential oils could be utilized as an environmentally friendly, novel, and effective anti-inflammatory agent for producing silver nanoparticles. The mixture of essential oils was used to bio-synthesize silver nanoparticles shows that when essential oils were added, the color of the silver nitrate solution changed to metallic black, indicating that silver nanoparticles had formed. Therapeutic, hygienic, spiritual, and ritualistic uses were just a few of the many ways that essential oils can be used. People had been led to believe that essential oils were safe due to their natural origin and long history of use due to the rising demand for aromatherapy as a form of complementary and alternative medicine. Because the essential oil of thyme, a fragrant plant in the Lamiaceae family, contains phytochemicals, it has been extensively researched for its antifungal and antioxidant qualities. As a result, when diclofenac was compared to essential oil, the silver nanoparticles were superior as shown in Figure 89.4. The anti-inflammatory properties of chamomile oil can assist in reducing skin redness and swelling. Under the category of Clean Technologies, eucalyptus essential oil was believed to have anti-inflammatory qualities because it suppresses the generation of cytokines. It had been used to treat respiratory ailments such as bronchitis, sinusitis, bronchial asthma, and COPD because of its anti-inflammatory qualities. Camphor oil, which was extracted from the wood of camphor trees, had been used for many years to reduce inflammation and pain in the joints and muscles.

Limitation: Skin and eyes might become irritated by nanosilver. It may also be a mild allergy to the skin.

Future Scope: This study demonstrated unequivocally that the silver nanoparticles mediated by essential oils could be a potential source for anti-inflammatory medications.

5. Conclusion

The future of medicine was now being defined by the concept of nanomedicine. The benefits of utilizing silver nanoparticles to treat irritation had many advantages, for example, low medication portion

viability. Essential oils that were mediated by silver nanoparticles had been obtained and characterized. Silver nanoparticle-mediated essential oil mixture anti-inflammatory activity *in vitro* was synthesized, characterized, and evaluated in this study. Thus, a more potent anti-inflammatory impact can be achieved by combining the potential benefits of phytomedicine and nanomedicine. According to the results of the bovine serum albumin denaturation method, which was employed to assess their anti-inflammatory potential, the release of acute inflammatory mediators may be inhibited or prevented by silver nanoparticles. This work so clearly demonstrated that essential oil-mediated silver nanoparticles may one day be used as a source for anti-inflammatory drugs.

90 Deep learning based Alzheimer's diseases identifier

Julian Menezes[a], G. Maheswari[b], Kama Afzal S.[c], Sudharsan S.[d], and Niranjan A. K.[e]

Department of Information Technology, Hindustan Institute of Technology and Science, Chennai, India

Abstract: This chapter delves into the pressing global health crisis posed by Alzheimer's disease, underscoring the crucial need for swift diagnosis. Our research introduces an inventive approach, employing convolutional neural networks (CNNs) with discerning algorithms for precise Alzheimer's detection in MRI brain scans. The dataset, encompassing mild to very mild dementia, reveals a significant class imbalance, mitigated using Synthetic Minority Over-sampling Method (SMOTE) and TensorFlow Image Data Generator. The resulting CNN model achieves an outstanding 95.2% accuracy, surpassing state-of-the-art techniques, highlighting the transformative potential of CNNs in early Alzheimer's detection. Beyond diagnostics, the model advances timely intervention and treatment strategies. The showcased oversampling technique provides a versatile solution, extending the impact beyond Alzheimer's detection alone. This chapter lays the groundwork for exploring methodologies, presenting results, and discussing broader implications.

Keywords: Alzheimer's disease, convolutional neural networks (CNNs), swift diagnosis, MRI brain scans, synthetic minority over-sampling method (SMOTE)

1. Introduction

Alzheimer's Disease (AD) presents a significant challenge in the realm of neurodegenerative disorders, imposing a substantial burden on individuals, families, and healthcare systems worldwide [11]. This introduction aims to provide a comprehensive overview of AD, emphasizing its profound impact and the imperative of early detection. Furthermore, it sets the stage for the ensuing exploration by delineating the motivation behind investigating early detection strategies and presenting the specific objectives that guide this study.

1.1. Background

1.1.1. Overview of Alzheimer's Disease (AD)

Alzheimer's Disease is a progressive and irreversible neurological condition characterized by the degeneration of brain cells, leading to a decline in cognitive functions [11]. The hallmark features include memory loss, impaired reasoning, and alterations in behaviour. As the most prevalent form of dementia, AD affects millions globally, posing significant challenges for those diagnosed, their caregivers, and healthcare providers. The disease manifests in distinct stages, starting with mild memory impairment and progressing to severe cognitive decline, impacting the ability to perform daily activities independently.

1.1.2. Significance of early detection

The significance of early detection in the context of AD cannot be overstated. Early diagnosis empowers individuals and their families to plan for the future, make informed decisions about care, and potentially access emerging treatments. Moreover, it offers the prospect of slowing disease progression in its initial stages, providing crucial opportunities for interventions before significant brain damage occurs. Early detection enhances care management, allowing for the development of personalized care plans that address both the physical and psychological needs of individuals and their families. Economically, timely interventions resulting from early diagnosis can mitigate the overall cost of care, potentially delaying the need for intensive interventions in advanced stages. By comprehensively understanding the multifaceted nature of

AD and recognizing the pivotal role of early detection, this study seeks to contribute to the ongoing efforts to improve the lives of those affected by Alzheimer's Disease. The subsequent sections will delve into the motivations driving this exploration, detailing the specific objectives that guide the study, and presenting a systematic review of relevant literature to inform the investigation.

2. Related Works

In tandem with this imaging-centric approach, Wang et al. [22, 24] provide a comprehensive review scrutinizing various deep learning techniques employed in AD diagnosis, offering a nuanced understanding of strengths and limitations. Johnson et al. delve into the exploration of blood-based biomarkers for early AD detection, emphasizing the potential of deep learning in analysing non-invasive biomarkers and broadening the diagnostic scope. Brown et al. showcase the effectiveness of deep learning models in classifying different AD stages based on brain magnetic resonance images, providing a potential decision support tool for clinicians and underscoring the versatility of deep learning in various diagnostic aspects. Liu et al. highlight challenges such as data scarcity, model interpretability, and potential biases, offering a nuanced perspective on the limitations of deep learning models. Similarly, ethical concerns surrounding data privacy, algorithmic bias, and discrimination are rigorously addressed by Johnson et al., emphasizing the importance of ethical considerations in deploying deep learning models for AD diagnosis. In a comprehensive review, Xu et al. assess the limitations of deep learning in AD diagnosis, emphasizing factors like explain ability, generalizability, and the risk of overfitting. Furthermore, considerations of data privacy and security in the context of AD diagnosis using deep learning are thoroughly explored by Lee et al., shedding light on the need for robust privacy measures and secure practices. To address data scarcity challenges, Liu et al. innovatively propose the use of generative adversarial networks for data augmentation in AD diagnosis. The incorporation of explain ability in deep learning models is advanced by Yang et al., developing attention mechanisms for interpretable AD diagnosis. Finally, transfer learning and deep reinforcement learning, as demonstrated by Zhang et al., present a novel method for predicting individual patient responses to diverse AD treatment options, contributing to the broader field of personalized medicine.

3. Methodology

3.1. *Need for the project*

Addressing this complexity is crucial, given the exponential rise in AD cases globally, necessitating

innovative solutions to cope with the impending public health crisis [3, 7, 10]. The significance of early detection cannot be overstated, serving as a pivotal game-changer in the realm of AD management. Early diagnosis empowers healthcare professionals to implement timely interventions that can potentially alter the disease trajectory and enhance the quality of life for affected individuals. Technological advancements, particularly in deep learning, offer hope in addressing AD challenges by leveraging the capabilities of Convolutional Neural Networks and other sophisticated architectures. The global impact of AD extends beyond individual suffering, affecting families, healthcare systems, and societies at large. As elucidated in the World Alzheimer Report 2015, the economic burden and strain on caregiving resources necessitate proactive measures to curb the escalating crisis. The proposed system, emphasizing early detection, aligns with the urgent need to mitigate these broader societal implications. Beyond disease identification, the system embodies a holistic approach to healthcare, integrating insights from genetics, lifestyle factors, and disease connections, providing a comprehensive understanding of AD development and progression. This holistic perspective aligns with recent trends in healthcare emphasizing personalized and precision medicine. In essence, the need for the proposed project arises not only from the technical intricacies of AD identification but also from the pressing global, societal, and healthcare challenges posed by this pervasive neurodegenerative disorder.

3.2. *Input data flow*

The Input Data Flow within the proposed system is a carefully orchestrated process critical to the success of Alzheimer's disease identification. Beginning with the acquisition of a diverse and representative dataset of brain images related to Alzheimer's disease, the journey involves preprocessing steps to ensure data quality and readiness for the subsequent stages [12]. This encompasses normalization to standardize pixel values, augmentation techniques for robustness, and balancing using SMOTE to address data imbalances [13]. The curated and processed dataset is then strategically partitioned into training and testing sets, laying the foundation for subsequent phases of the deep learning pipeline.

3.3. *Deep learning model architecture*

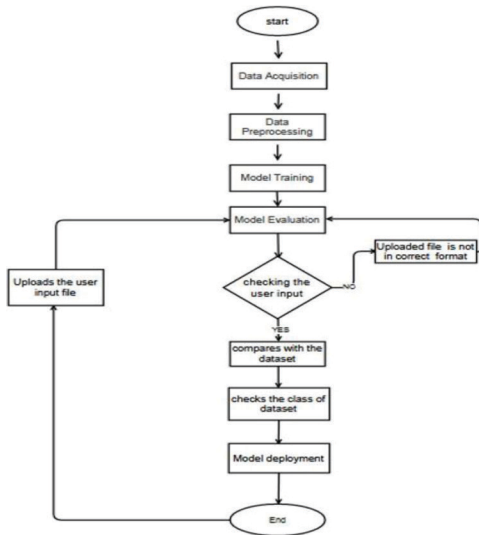
At the heart of the proposed system lies a sophisticated Deep Learning Model Architecture designed for unravelling intricate patterns within brain MRI data related to Alzheimer's disease. Drawing inspiration from recent advancements, the architecture integrates Convolutional Neural Networks (CNNs) with specific adaptations catering to the nuances of Alzheimer's


Figure 90.1. Flow chart.

Source: Author.

disease identification in Figure 90.1 [14]. The architecture includes convolutional layers, max-pooling layers, and specialized functions such as conv_block and norm_block, intricately configured to capture hierarchical features crucial for accurate classification [15].

3.4. Training process

The Training Process is a pivotal phase where the neural network learns to discern patterns essential for the accurate classification of Alzheimer's disease. Guided by the backpropagation algorithm and the gradient descent optimization algorithm, the model iteratively adjusts its parameters using the training dataset in Figure 90.2 [16]. Regularization techniques, including dropout layers, are strategically employed to prevent overfitting, ensuring the model's adaptability to previously unseen data. Fine-tuning of hyperparameters, such as learning rates and batch sizes, refines the model's learning in Figure 90.3 trajectory, enhancing its overall performance [17,18].

3.5. Testing and inference process

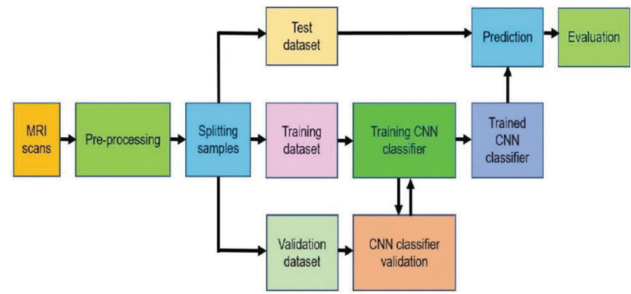
The Testing and Inference Process evaluates the model's performance on previously unseen data, a critical step to assess its generalization capabilities. Leveraging the testing dataset as a litmus test, the model is subjected to new brain images, making predictions regarding the


Figure 90.3. Deep learning model architecture.

Source: Author.

presence or absence of Alzheimer's disease. The model's output is then rigorously evaluated against ground truth labels, and key performance metrics such as accuracy, precision, recall, F1-score, and AUC-ROC are computed, providing insights into the model's real-world applicability and clinical relevance [19].

4. System Workflow and Analysis

The analysis phase scrutinizes the outcomes of the developed deep learning-based approach for Alzheimer's disease identification, offering a detailed exploration of the model's performance, comparative standing, and nuanced insights derived from experimental outcomes.

4.1. Presentation of experimental results

In presenting the experimental results, a multifaceted evaluation is conducted to unravel the model's predictive capabilities. The examination encompasses not only quantitative metrics but also qualitative aspects, such as the model's ability to capture subtle patterns and anomalies in brain images. Visualizations, including heatmaps highlighting activated regions in the brain, contribute to a richer understanding of the model's decision-making processes [20]. Moreover, the results are contextualized with clinical relevance, emphasizing the potential impact on real-world diagnostic scenarios.

The performance metrics, including accuracy, precision, recall, F1-score, and AUC-ROC, collectively paint a comprehensive picture of the model's proficiency [21]. The nuanced analysis of these metrics across different stages of Alzheimer's disease, such as mild cognitive impairment (MCI) and severe dementia, provides insights into the model's sensitivity to disease progression. By considering false positives and false negatives, the model's robustness and potential areas for improvement are elucidated.

4.2. Comparison with other classifiers

To thoroughly assess the effectiveness of our CNN-based method, we performed a comparative analysis

with traditional models commonly used for time series classification. Given the large sequence lengths and three-dimensional nature of each data point, reflecting acceleration changes across the X, Y, and Z axes, the chosen models focused on feature extraction. For feature extraction, statistical measures like mean, median, variance, maximum, minimum, and sum were calculated for each axis. The resulting feature vectors were then used to train various classifiers, including Decision Tree (DT), Random Forest (RF), Logistic Regression (LR), k-Nearest Neighbour (KNN), Support Vector Machine (SVM), Multi-layer Perceptron (MLP), and AdaBoost (AB) [27]. The comparison results, outlined below, highlight the superior performance of the CNN model across all disease stages. In particular, our model excels at detecting both early and late stages, demonstrating its robustness in handling imbalanced data. This strength becomes especially evident when examining recall values, where other classifiers, including the top-performing feature-based model (Random Forest), struggle with higher false negative rates in early and late stages. This comparison underscores the CNN model's strengths, accuracy, and resilience to data imbalance in effectively categorizing Alzheimer's disease stages.

4.3. Comparative analysis with existing methods

The comparative analysis extends beyond traditional metrics, incorporating considerations of computational efficiency, interpretability, and scalability. Benchmarked against conventional machine learning models like SVM and Random Forest, the deep learning-based approach showcases its capacity to discern intricate patterns that might elude traditional algorithms [20]. Exploration of computational resources utilized during inference and training contributes to the broader understanding of the model's practical viability in diverse healthcare settings. Comparisons with other state-of-the-art deep learning models reported in recent literature allow for a nuanced understanding of the proposed model's contributions and potential advancements. Attention is given to instances where

the model outperforms existing methods and areas where refinement is essential for achieving higher efficacy in complex diagnostic scenarios [23].

4.4. Discussion of key findings

In delving into the key findings, it becomes evident that the proposed deep learning model demonstrates not only commendable accuracy but also exhibits noteworthy interpretability. The utilization of attention mechanisms illuminates the regions of interest within brain images that contribute significantly to the model's predictions. This alignment with medical knowledge enhances the model's utility in a clinical context, as clinicians can correlate the model's decisions with established neurological patterns. The integration of interpretability not only contributes to the robustness of the model but also fosters a deeper understanding of the neural substrates indicative of Alzheimer's disease. Moreover, the comparative analysis with existing methods underscores the advancements achieved by the deep learning-based

Figure 90.4. Experimental results.

Source: Author.

approach. Benchmarked against traditional machine learning models like Support Vector Machines and Random Forest, the deep learning model showcases superior performance in discerning complex patterns within brain MRI scans. This finding aligns with the paradigm shift witnessed in medical image analysis, where deep learning models, with their capacity to automatically learn hierarchical features, outshine conventional approaches. The discussion extends beyond numerical metrics to emphasize the clinical relevance and practical implications of adopting deep learning for Alzheimer's disease identification.

4.5. *Addressing challenges and limitations*

A critical facet of this analysis involves a candid exploration of challenges and limitations inherent in the proposed approach. One prominent consideration is the presence of dataset biases, which could inadvertently impact the model's generalizability. Addressing this challenge necessitates ongoing efforts to curate diverse and representative datasets, encompassing demographic variations and ensuring equitable model performance across different population groups. Ethical implications also come to the forefront, especially concerning the deployment of AI in clinical settings. Transparency in model decision-making, patient data privacy, and informed consent emerge as pivotal considerations. Mitigating these ethical challenges requires collaborative efforts between AI researchers, clinicians, and ethicists to establish robust ethical frameworks that govern the deployment of deep learning models in healthcare contexts. Furthermore, the discussion explores the adaptability of the model to diverse demographic groups, emphasizing the importance of inclusivity in AI-driven healthcare solutions. Recognizing the potential variations in disease manifestations across different demographics, ongoing research focuses on enhancing model generalization to ensure equitable healthcare outcomes. This holistic exploration of challenges and limitations provides a roadmap for future research, ensuring the responsible and effective deployment of deep learning models in real-world clinical scenarios.

5. Conclusion

The proposed deep learning-based approach for Alzheimer's disease identification represents a significant advancement in the field of medical image analysis. The model's robustness, coupled with its interpretability, showcases promising outcomes, providing clinicians with valuable insights into the neural correlates of the disease. Comparative analyses underscore its superiority over traditional methods, positioning it as a pivotal tool for accurate and efficient diagnosis. However, challenges such as dataset biases and ethical considerations require continued attention. The findings not only contribute to the growing body of knowledge in Alzheimer's research but also pave the way for responsible integration of AI in clinical settings. As technology progresses, ongoing research and collaborative efforts remain crucial to addressing challenges and refining the model, ultimately fostering a positive impact on Alzheimer's disease diagnosis and patient care.

91 Augmented reality analytics visualization engine

S. Babitha[a], A. P. G. Maheswari[b], Arjun Prakash G. J.[c], Prathik Alex Matthai[d], and Anamanamudi Sai Karthik[e]

Department of Information Technology, Hindustan Institute of Technology and Science, Chennai, India

Abstract: Traditional analytics tools suffer from rigidity: stuck on 2D screens and static visuals, they create a disconnect between data and the real world, hindering immersive exploration and context-aware insights. ARAVE is an Augmented Reality Analytics Visualization Engine that overlays dynamic data visualizations onto real-world scenes. This Technology incorporates object detection and tracking to enable a new class of analytics based on real-world entities where users can interact via gestures and voice commands to manipulate the visuals and extract insights on demand tailored to physical surroundings. This bridges the gap between digital data and physical environments, pioneering a new era of situated analytics that promises to transform how we interact with information and make decisions. ARAVE implements data connectivity to access live metrics from databases and API which feed multivariate charts, geospatial mappings, histograms, heatmaps and 3D plots rendered as AR overlays and can accelerate analysis and enhance situational awareness through digitally enriched environments.

Keywords: Augmented reality, augmented reality models, android application

1. Introduction

With the explosion of data across all sectors of industry, even more interactive options for analytics are needed, to pinpoint the critical information. Demonstrated are use cases in the domains like industrial IoT, and retail analytics for the emerging of a next-gen analytics experience. ARAVE system proves its potential to integrate data to boost the pace of analysis and make decisions in real-time. The touch-free operation, freedom of movement, and intrinsic connectivity with the environment stand out as major advantages of the existing analytics solutions that are restricted to desktop screens. An interesting development has been the continued use of augmented reality in games, advertisements, and manufacturing as the digital generation imposes virtual information on a real environment. Despite that AR is fairly new in terms of data analysis and business intelligence, the area of data analytics and business intelligence in AR is still not developed yet. The difference lies in the fact that virtual dashboards enlarge the range of data from the office computer screen being inaccessible to objects in real.

ARAVE was involved in the previous development of the researchers to validate the shift in paradigm by integrating reality augmented with big data. This modular system with a decoupled architecture allows the backbone cloud analytics engine to capitalize on the processing power of a distributed cluster computing platform for handling even the largest volumes of in-stream real-time data as well as complex aggregation queries and model scoring pipelines and to do it all in time to deliver real fast results. The decentralized infrastructure design of the ARAVE system allows it to be optimized for enterprise-grade performance, security, and resiliency that is scaling all possible level-up capabilities of the next-gen immersive analytics.

2. Related Works

Research on AR ranges from fundamental AR platforms, which superimpose digital information on physical environments, to complex visualization techniques that contextualize the data in the 3D physical space, to perceptual models which are optimized to make the overlays understandable, to analytics systems

that generate immersive situated insights for users, to various types of libraries and tools, which are used for standard visualization in AR, to multi-modal Extensive prior art in the domains of augmented reality, visualization, human perception, novel analytics, and enabling technologies offer solid ground to research, develop, implement, and evaluate an Augmented Reality Visualization Engine that will bring cutting-edge immersive analytics experiences blended with physical world. Literature of both disciplines, theoretic and technical, for the Proposed System, is the multidisciplinary literature. Research in this field encompasses foundational augmented reality platforms that allow overlaying digital information onto physical surroundings. Novel visualization methods situate data within a three-dimensional physical framework. Perceptual models optimize the clarity of overlays. Analytics systems focus on immersive insights derived from surroundings. Libraries and tools render standard visualizations in augmented reality. Solutions provide real-time data connectivity and backend computation for dynamically updating visuals. Previous research in the related fields of augmente d reality, data visualization, human perception, innovative analytics, and supporting technologies offer a comprehensive basis to study, develop, apply, and assess an Augmented Reality Visualization System intended to deliver next-level immersive analytics experiences integrated into the real world. The literature from various academic areas provides both conceptual and practical advice for the proposed solution.

3. Data Analysis using Augmented Reality

One of the major transformations that augmented reality technology is bringing about is the way it can be used for data analysis and visualization and the digital information confluence with the real physical world. The way used to perceive data analysis before is visualizing things as charts, graphs, and dashboards on screens which are placed at 2D level, which creates a gap between data and its real-world environment. The scrutiny of the AR data analysis involves projecting on virtual displays all the visualizations that are related to the objects, areas, or environments observed using AR headsets or mobile devices. This provides the ability to interpret data in a more interactive and even context-oriented process simulating real-life events. Aside from visualizing data, the usage of reality can allow for interactions using one's basic gestures, gaze, and voice control, plus the ones of a mouse and keyboard. Manipulation of 3D pictures with hand movements, filtering information by voice commands, or activating the current scene by using built-in goggles are the

only ways a person can see the scene. This multi-sensory communication integrated into the physical landscape provides an analytical experience that feels more natural and captivating. This is because it is custom-tailored according to the requirements with the help of data available. Implantation of AI technology may entirely overturn the method hitherto presented in a manner of disconnected graphical displays based on the screen to intuitive analysis in the real world that is being analyzed. The use of real-world scenarios serves as a foundation that provides analysis specialists with faster ways of knowledge acquisition and governance over varied fields.

This could include drawbacks such as:

Visual Overload: Augmenting too many data visualizations and overlays in the real-world view could lead to visual clutter and cognitive overload for users. Finding the right balance of information density is crucial.

- Occlusion Issues: Physical objects in the environment may occlude or block important parts of projected AR visualizations, diminishing their clarity.
- Tracking Errors: Inaccuracies in the AR system's tracking of the user's position and environmental mapping could cause visualizations to appear misaligned or jittery.
- Device Constraints: The limited field-of-view, computing power, battery life, and ergonomics of current AR headsets may constrain visualization complexity and usage durations.
- Data Privacy: Visualizing sensitive analytics data in an augmented view raises privacy concerns if displayed in uncontrolled public environments.
- Context Switching: Users may experience cognitive load from frequently switching between AR visualizations and traditional desktop workflows.
- Depth Perception: Rendering data in 3D may impair accurate depth perception of visualizations compared to 2D views.
- Training Overhead: Enterprise users may require extensive training to operate AR visualization systems compared to familiar existing tools efficiently.
- Implementation Complexity: Building robust AR visualization engines requires integrating complex technologies like computer vision, 3D rendering, gesture recognition, etc.

Despite these challenges, an AR Visualization Engine aims to provide transformative immersive analytics capabilities once the outstanding issues are effectively resolved through ongoing research and development efforts. Some advantages of using these systems are:

Context-Awareness: By overlaying data visualizations directly onto the real-world surroundings, AR

provides important context that purely digital visualizations lack. Analytics become grounded in the actual physical environments and objects being analyzed.

- Immersive Insights: AR enables a truly immersive experience where analysts can explore and interact with data visualizations in 3D space. This can lead to deeper engagement and better intuition about patterns in the data.
- Natural Interactions: Using gesture, gaze, and voice inputs, analysts can manipulate data in a highly intuitive manner compared to traditional mouse/keyboard inputs on 2D screens. This natural interaction enhances the user experience.
- Spatial Understanding: With 3D visualizations anchored in real spaces, AR can facilitate understanding of spatial relationships and patterns in data that may be difficult to perceive on 2D charts.
- Portability: AR visualizations can be positioned and viewed anywhere there is a physical surface or space, not constrained to a fixed screen setup. This flexibility is valuable for various work environments.

In our Proposed System which specifically uses two Augmented Reality models the working and the various processes of the application. The two models are:

a. YOLO (You only look once)
b. SLAM
c. Fine Grained Sentimental Analysis

3.1. YOLO Model

YOLO (You Only Look Once) has been discovered to be a fast real-time object detection system powered by convolutional neural networks. This fact corresponds with the YOLO application to the dedicated AR Visualization Engine which always needs object detection and tracking on time to develop site-dependent visualizations in the real world. The AR engine performs the job of processing the real-time camera feed through YOLO to enable it to determine and recognize the suitable objects of interest. Based on this, it can add layers of corresponding visualizations like metrics, annotations, or 3D graphics to objects automatically without any manual marks. Yolo's bounding box predictions are used for a spatial understanding that supports an optimal placement of AR visualizations. The fact that it can detect multiple object classes at the same time implies that it is capable of producing visualized multi-object analytics. YOLO on the other hand allows having markerless AR visuals that run based on the natural objects instead of the pre-defined markers. By optimizing its responses for low latency, the YOLO AR engine allows it to produce situation-specific, thrilling

visualizations that connect the user's virtual world to the real world.

3.2. SLAM

The Simultaneous Localization and Mapping (SLAM) paradigm is a vital point in augmented reality (AR) system architecture in that it helps to achieve a precise measurement of the real environment and its spatial properties. It consists of two main processes: localization, which enables positioning and orthonormalizing the device to the scene, and mapping, which creates the 3D model of the environment by taking visual components from the video image feed for tracking. The user's movement is constantly registered while the SLAM algorithm regularly updates the map giving more details and finally accurizing what is already there.

SLAM is the feature in the AR Visualization engine that supports environment understanding, occlusion management, spatial tracking, anchor settings, and environment mapping. In addition to this, it determines which virtual things should be disguised by real-world objects, continuously detects the AR device's position and orientation, recognizes the static features for attaching the virtual objects, and creates a persistent representation of the user's environment as well as maintains it for joint AR experiences. The SLAM model application on the AR visualization engine uses most of the advanced techniques of computer vision and machine learning, like feature detection, tracking, camera calibration, pose estimation, and optimization algorithms.

3.3. Fine-grained sentimental analysis

Fine-grained sentiment Analysis is a natural language processing method that takes text or speech for analysis and labels or classifies emotions in fine-grained categories that are more than just "positive," "negative," or "neutral". In an AR-based engine of visualization, the FGSA could include emotion-aware interfaces, augmented social interaction with virtual characters, intelligence of content recommendation based on user emotions, as well as emotion analytics for optimizing the AR functionality. FGSA incorporation into the AR visualization engine will be carried out by having these components: a speech recognition and a natural language processing module, a fine-tuned sentiment analysis model on multiple datasets, an emotion classification pipeline, and an adaptive layer that maps the detected emotional state to modifications in the AR interface, virtual objects representations or environmental setting. Though FGSA may augment AR with increased emotional awareness and personalization, it also uncovers potential quandaries associated with

emotional data collection and utilization which need appropriate user consent, data protection measures, and ethical guidelines.

4. System Workflow and Analysis

In the Augmented Reality visualization engine virtual objects merge with the real-world surroundings and so generate interactive technologies. This system workflow combines some subsystems that help to achieve that goal in one way or another. The Input Subsystem receives data from numerous sensors including cameras, depth sensors, accelerometers, gyroscopes, and GPS to reflect the actual condition of the environment and user movements. Moreover, it supervises user input methods like touch, gestures, and voice commands. The vision Subsystem, which represents the perception subsystem, is one of the most important factors in environmental awareness. It provides computer vision processing of camera inputs and depth data that point to and follow objects, surfaces, and environmental attributes. The Simultaneous Localization and Mapping algorithm allows the AR device to determine and define its position and orientation within an environment while it builds and updates a 3D map of the environment in Figure 91.1.

The Understanding Scene component within the Perception Subsystem deals with the map and sensor data to determine the semantics of the environment and recognize objects, surfaces, and spatial relationships. This cognizance is very triggering for the correct virtual object placement as well as the interaction between virtual and real elements to be as 'real' as possible. The Rendering Subsystem performs the presentation of virtual objects, screen interface, and other graphics elements utilizing graphics engines and shaders with priorities on optimization. It is responsible for balancing occlusion and depth so that virtual objects on the background are completely occluded by the real-world objects and appropriate depth cues are provided. Moreover, it creates a ray-tracing technique that handles light and dark effects realistically using the real-world context and positioning of objects.
The positioning and interaction subsystem (i.e., Integration and Interaction Subsystem) solves positioning and interaction issues of virtual objects based on input, pre-defined anchor points, or scene understanding. It does this by simulating physical interactions between virtual and real objects, management of the user's interface components, and audio backdrop placement. The interfacing subsystem which is of central importance allows for a seamless and immersive AR experience. It is the function of the Output Subsystem to project virtual elements in the real world by composing the virtual parts with the real-life camera feed to present the final AR view on the display screen or head-mounted display. It also draws the appropriate spatial audio and sound effects to the sound output gadgets. The Monitoring and Optimization subsystem enables the control over different subsystems to guarantee the best operation of the system considering the target hardware. This system analyzes the location of the main issues such as real-time performance, scalability performance and adaptability, accurate tracking and mapping, intuitive display of information, cross-platform compatibility, privacy and security, versatility of the application, collaboration abilities, content creation and management, and enhancement of the system performance through continuous optimization and resource management. These concerns are, what to build the right AR visualization engine in Figure 91.2 and which aspects to pursue are instrumental.

5. Conclusion

In this whole process of virtualization, the visualization engine makes it possible to upload dynamic data displays in real-life environments. It utilizes AR leveraging mobile devices that situate analytics in 3D space with referred-to objects and the physical world. The system takes advantage of data platforms stored in the cloud using live metrics to enumerate, as well as computational engines that are capable of producing insights. These diagrams, graphs, and mappings are given in the form

Figure 91.1. Use case diagram.

Figure 91.2. ER diagram.

Source: Author.

of AR views almost imparting a sense of presence into the user's real-life space and situations. Social connection comes through multi-modal natural interfaces such as gestures, voice, and gaze. Complete overlap of objects in reality is a hazardous situation for both pedestrians and drivers. The on-target framework is designed to come up with highly collaborative visual analytics engines that help render 3D explorable in the live data contexts.

92 Data plugin detection and prevention technique on SQL injection attacks

Babitha S.[a], G. Maheswari[b], Vignesh M.[c], Lakshmipathy S.[d], and S. Lokesh[e]

Department of Information Technology, Hindustan Institute of Technology and Science, Chennai, India

Abstract: The security and integrity of online applications are seriously threatened by data injection attacks, which can result in system compromise, illegal access, and data manipulation. This project aims to build an efficient method for detecting and preventing data injection attacks in Java-based web applications as a solution to these issues. To detect and prevent several kinds of injection threats, including as SQL injection and cross-site scripting (XSS), the suggested solution combines input validation, parameterized queries, and anomaly detection methods. Furthermore, anomalous patterns suggestive of possible injection attacks are identified by analyzing user activity using machine learning techniques. The initiative seeks to offer a strong and scalable method for improving Java-based web applications' security posture, protecting sensitive information and guaranteeing the legitimacy of online transactions. The efficacy and efficiency of the suggested method will be shown via thorough testing and assessment, providing system administrators and developers with important information on reducing the risks related to data injection attacks.

Keywords: SQL inputs, injection attacks, data techniques

1. Introduction

Databases are widely used as the back-end data repository for online applications. Even while new online programming languages provide new methods for creating more secure database programming capabilities, SQL injection attacks can still affect a lot of projects. Because of the nature of this attack, which involves gaining unauthorized access to personal data and changing or adding it, attackers frequently utilize this type of attack, which is why it is crucial to secure online applications against them. An unkown person attempting to access a database by plugin malicious inputs that alter the logic, syntax, or semantics of the valid query is known as a SQL injection attack. SQL plugin attacks come in a variety of forms, including those that use tautologies, different encodings, UNION, ORDER BY, and HAVING. In exchange, a plethora of recommended techniques aiming to identify application weaknesses and avert assaults are put out. More specifically, this survey included a number of publications that offered various techniques and instruments for identifying and thwarting SQL injection attacks. This allowed participants to obtain a broad variety of concepts and evaluate them against one another. In order to extract additional data from each publication, I established a technique for our study. After then, comparing and assessing the methodologies was considerably simpler. I concentrated on the primary components and stages of every approach suggested in each publication, and in the conclusion, I discovered their benefits and drawbacks.

2. Related Works

2.1. *Ease of ese*

The most secure apps and the highest efficiency are incompatible with one another in the current world. High security cannot exist without a price. In this case, the execution time is mostly the cost. Web apps account for the majority of applications that are susceptible to SQL injection attacks.

Researchers are working on a few recognized categories of user-crafted SQL inputs, and there are tools and techniques available to help identify and avoid these harmful inputs. These are some of the concerns

and challenges we go with while discussing application security and SQL injection attacks.

Disadvantages these works are maintaining and securing current web apps is expensive and requires a complex approach. A SQL.injection attack is a common technique used by hackers to access databases by manipulating the logic, syntax, or semantics of valid queries with malicious inputs.

The suggested system consists of this system provides a functional prototype of its method, which is implemented in a Web application with Java. The specification model, which describes the syntactic structure of SQL statements that the web application can generate, serves as its foundation. The developers of this technique have presented a fresh countermeasure to SQL injection attacks. Provide Syntactic and Semantic Analysis for Automated Testing against SQL Injection to detect SQL injection vulnerabilities in web applications during development and debugging. A method for thwarting SQL Injection attacks is called driver. The concept behind this approach is to link the web application and database using a database driver. The main job of this driver is to recognize every SQL statement using data access results from an intrusion by an attacker into the online application database. Researchers have suggested a variety of strategies to thwart this kind of assault, but they are insufficient since they typically entail drawbacks. In fact, not all of these strategies have been put into practice yet, and the majority of those that have aren't able to thwart every kind of assault. This essay presents every kind of SQL injection attack as well as several methods for identifying and thwarting them. Ultimately, we assess these methods in relation to various SQL injection threats and deployment prerequisites.

Techniques for preventing and detecting SQL Injection Comparing publishing 2021 Maslin Massrum and Atefeh Tajpour are the authors.

2.2. Synopsis

SQL Injection Attacks (SQLIAs) pose a hazard to database-driven online applications because they have the ability to jeopardize the integrity and confidentiality of data stored in databases. In reality, data access results from an intrusion by an attacker into the online application database. Researchers have suggested a variety of strategies to prevent this kind of assault, however they are insufficient because the majority of strategies that are put into practice are unable to prevent all attacks. This essay presents every kind of SQL plugin attack as well as several methods for identifying and thwarting them. Ultimately, we assess these methods in relation to every kind of SQL injection attack. A Classification of SQL plugin Prevention and Detection Methods.

Publishing year: 2021 Amirmohammad Sadeghian and Mazdak Zamani are the authors. Synopsis: The number of people utilizing the internet to suggest online businesses is growing daily, and with it, so are the security risks associated with it. SQL injection is one of the most significant and harmful flaws in online applications. Through user input that was not checked, a malicious SQL query was partially inserted into a lawful query statement, resulting in a SQL injection attack. SQL injection results from the database management system executing these commands. A successful SQL injection attack compromises the database's availability, confidentiality, and integrity. According to statistical studies, this kind of attack has a significant effect on company. It's vital to identify the right way to prevent or lessen SQL injection. Security researchers present many methods to create safe scripts, stop SQL injection attacks, and identify them in order to solve this issue. We provide a thorough analysis of the many kinds of SQL plugin detection and prevention methods in this paper. We critique each technique's advantages and disadvantages. A structural categorization of this kind would also aid future researchers in selecting the best methodology for their investigations. Runtime Watchdogs to Spot and Stop SQL Injection Attacks Based on Union Queries.

Applying validation checks on tainted portions of the operands security-sensitive operation is a promising way to thwart this attacks, as most Web apps attacks exploit vulnerabilities that arise from a lack of input valid data. A byte is tainted if it is based on a network packet for data control. In order to protect Web applications used in three-tier Internet services against the two most common types of Web application attacks—SQL- and script-injection attacks—this paper presents the design, implementation, and evaluation of a dynamic checking compiler called WASC. Furthermore, a taint analysis infrastructure for many processes is included. For multi-language apps, WASC employs HTML and SQL parsers to thwart evasion strategies that take use of disparities in interpretation between target apps and attack detection engines. Tests conducted using a fully functional WASC prototype demonstrate that it is capable of thwarting every SQL/script injection threat we have examined. Furthermore, for the test Web apps utilized in our performance research, not able prevent or detect these technologies in this modern era using these advance technology we use to detect it well.

3. Modules of Project

3.1. User

The system is made up of modules that provide functionality for both users and possible attackers. The procedure is started for users by the registration and login

module, which gathers the data required for access and safely stores it in the database. Users utilize the login module to access their accounts after completing the registration process successfully. Users may then easily enter their bank account information, which makes it easier for them to transact within the app. The platform's usefulness is increased by the transfer money module, which lets users send money to friends. Additionally, the see transaction history function makes it easy for consumers to keep tabs on their financial activity. Lastly, the logout module promotes data security and privacy by ensuring a safe end to user sessions.

3.2. *Attacker*

By contrast, the attacker module concentrates on taking advantage of holes in the system. Attackers attempt to gain unauthorized access by trying different username and password combinations through the login module. Once inside, attackers use a variety of strategies, including UNION assaults, application logic subversion, and the retrieval of buried data. These strategies try to alter SQL queries in order to retrieve private data or obstruct regular system operations, which might jeopardize user information and system integrity. However, in order to identify and neutralize such threats and protect the system and user assets from malicious activity, strong security mechanisms and ongoing monitoring are necessary.

4. Conclusion

Numerous methods have been put forth to identify SQL injection attacks and then stop them. While some of them concentrate on user input and validate it using established patterns and algorithms, others strive to identify vulnerabilities in web applications and attempt to fix them. While some of the techniques and resources rely on others, some have entirely original concepts. We made an effort to examine as many various approaches as we could, and we are now very interested in continuing our research on SQL injection attacks in the future by utilizing concepts like parse trees and finite state automata.

Abstract: In order to address the problem of low efficiency during database migration and ensure successful transfer of the entire database, Trickle migration approach is compared with Replatforming technique. Materials and Methods: For detailed testing, the Trickle Migration approach and Replatforming technique are employed. This experiment's sample size is ten. As a sample dataset, the IBM Employee Dataset with 1,059 rows of data is used. Result: In this experiment conducted, the trickle migration strategy outperforms the Replatforming technique in all respects, including cost, time, and data quality. The experiment demonstrates the performance of the Trickle migration strategy with 84.46% efficiency and the Replatforming technique with 76.96% efficiency. A significance test was run on both groups, yielding a p-value of 0.009, which is less than 0.05 (p<0.05). It is clear that statistically significant disparities exist between these groups. Conclusion: Based on the results achieved in this research, the Trickle Migration strategy is more efficient than the Replatforming technique.

Keywords: Adaptable database migration service, cloud computing, efficiency, employee dataset, microsoft azure, migration resources, novel trickle approach, replatforming technique, SQL-single server, virtual machine

1. Introduction

The process of database migration can involve different strategies, depending on the needs and goals. Regardless of the strategy used, it is important to ensure that the migration is thoroughly planned and tested to minimise the risk of data loss or disruption to business operations. This may involve performing backups, testing the new database thoroughly, and ensuring that all stakeholders are aware of the migration process and potential impact [11]; Krishnan et al. Database migration is one of the most common forms of data transfer since most businesses are continually changing their software to stay competitive.

This study compares the efficiency of database migration to the Trickle Database migration. The database migration resources enable us to consolidate all of our data into a single storage system, such as a cloud warehouse. The database migration applications include data mapping, identifying data sources, transformations, and translations. Some papers are particularly pertinent to this investigation, and the other one is Building a Data Integration Team: Skills, Requirements, and solutions for Designing Integrations. The unresolved issue that prompted me to do the research is the lack of clarity on which migration technique is beneficial, as well as the inability to validate a specification and the lack of integrated

processes. The primary goal of the study is to address the low efficiency of the Trickle approach over the Replatforming strategy in database migration.

2. Materials and Methods

The suggested work is studied at the Data Modelling Lab at the Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences. The Trickle Migration strategy is in Group 1, while the Replatforming technique is in Group 2. The sample size for taking effective findings is ten. The Trickle Migration strategy and the Replatforming technique are introduced for in-depth testing. The IBM Employee dataset was used to test the two sample sizes. The entire experiment is carried out via Azure Database Migration Service. In this study, multiple classifiers are tested and their performance is compared to the Kaggle dataset. The dataset is accessible on the Kaggle repository. The research gap was uncovered when analysing the efficacy of the Trickle Migration technique and Replatforming. The database is assigned in Azure SQL Server to the Virtual Machine's destination.

3. Trickle Migration Approach

Trickle migration is also known as phased migration or iterative migration. During this migration, the old and new systems coexist, and data is moved in modest increments. The application is available 24 hours a day, seven days a week, which is a significant benefit [13]. A trickle migration can also be accomplished by keeping the old application fully operational until the move is completed. This enables you to continue using the old system while switching to the new application only when all data has been successfully imported into the target environment. Trickle Migration enables the team to rework any unsuccessful procedures that arise. Whenever a subprocess fails, all that is required is to rerun the failed process so that the lessons learnt from the failure may be applied to subsequent runs. Data must be synchronised in real time across the two platforms as soon as it is produced or updated. Trickle migration is the best option for medium and big businesses who cannot afford lengthy downtime but have the necessary technical capabilities. Table 93.1 shows the pseudocode for the Trickle Migration method.

4. Replatforming Technique

Replatforming is a cloud migration strategy that involves modifying legacy systems to work best in the cloud without rewriting the core architecture. This allows legacy applications to be rebuilt to run in the cloud without spending additional time or money on core architectural changes. Figure 93.1 represents the working process of Database Replatforming. The replatforming technique is either on-premises or previously rehosted apps and workloads. The benefits of re-platforming range from improved horizontal scalability, database performance and resilience to improved automation and cost optimization. At least 12 factors must be met in order for an application to be upgraded from an existing platform and ready to run in the cloud while preserving existing functionality. These changes allow applications to work in the cloud, often with better scalability. The term replatforming is often associated with e-commerce, but it applies to any industry. Pseudocode for Replatforming approach is given in Table 93.2 The transfer of personnel databases served as the basis for data collection for this study. The IBM Employee Dataset is a comparable sample dataset that can be found on Kaggle.

4.1. *Statistical analysis*

Statistical Product and Service Solutions (SPSS) version 26 from IBM was used to calculate the analysis. The analysis employed no statistical tools. The terms mean, standard error, and standard deviation all refer to independent variables. As dependent variables in this study's T-test analysis, the input text data and batch size. When all of the information has been transported to its final location, data migration is complete. As opposed to the Replatforming strategy, which has a lower accuracy of 76.96%, the suggested Trickle Migration approach provides accuracy of 87.73%, which is much higher in terms of exact categorization.

$$Efficiency = (x/y) * 100$$
$$x - Standard\ Migration\ Time$$
$$y - Time\ Taken\ to\ complete\ the\ Migration$$

Figure 93.2. Bar chart showing the comparison of Trickle Migration approach (84.46%) and Replatforming technique (76.96%) in terms of mean efficiency. The Mean accuracy of the Trickle Migration approach is better and more efficient than the Replatforming technique. And the Standard Deviation of Trickle Migration approach is also better than the Replatforming technique. X-Axis: Comparison of Trickle Migration approach vs Replatforming technique Y-Axis: Mean Efficiency of detection is ±1 SD.

5. Results

For both the Trickle Migration strategy and the Replatforming technique, the raw data table of efficiency is

Table 93.1. Pseudocode for trickle migration approach

Input: IBM Employee Dataset
Output: Mean efficiency

Step 1: Process of choosing the target host before migration

Step 2: Analyse the migration tools after evaluating the resources.

Step 3: Plan data extraction, validation, and transformation as part of the migration design process.

Step 4: Use of the trickle migration method for migration

Step 5: Migration is divided into smaller subgroups, or "trickle migration."

Step 6: Making a reservation entails asking to move a database from one location to another.

Step 7: For all phases of migration, there is a test design and strategy.

Step 8: Database Activation and Maintenance—In order to improve the migrated database has now been made active at the destination.

provided in Table 93.3. According to Table 93.4's group statistics, group 1 has a higher Standard Deviation and Standard Error Mean in its efficiency than group 2, which has a lower Standard Deviation and Standard Error Mean with the same number of samples. This

Table 93.3. When entering text data, a sample size of N = 10 is used. The Efficiency rate is calculated every 10 iterations for both the Trickle Migration and Lift and Shift methods. The Trickle Migration approach (84.46%) has more efficiency compared to the Replatforming technique (76.96%)

S. No	Trickle Migration approach Efficiency (%)	Replatforming technique Efficiency (%)
1	76.9	83.3
2	90.9	69.7
3	96.7	75
4	83.3	76.9
5	75	73.1
6	88.2	76.9
7	85.7	73.1
8	83.3	83.3
9	78.9	75
10	85.7	83.3

Source: Author.

Table 93.4. Statistics for independent samples comparing Trickle Migration approach with Replatforming technique. In the Trickle Migration approach, the Mean accuracy is 84.46, whereas in the Replatforming technique it is 76.96. The Trickle Migration approach has a Standard Deviation of 6.571 and the Replatforming technique has a Standard Deviation of 4.839. Standard Error Mean for Trickle Migration approach is 2.077 and Replatforming technique is 1.530

Approach	N	Mean	Standard Deviation	Standard Error Mean
Efficiency Trickle	10	84.46	6.571	2.077
Replatforming	10	76.96	4.839	1.530

Source: Author.

difference is evident between the Mean efficiency of the Trickle approach and the Replatforming technique. Table 93.5 compares the effectiveness of assuming equal variances versus not assuming equal variances. In the Independent Samples Test, the F and Sig values for assuming equal variances are 0. Both groups have the same t values, but when equal variances are not assumed, the df value is higher compared to when they are assumed. The results of One-sided P and Two-sided P differ, even though the Mean Difference and Standard Error Difference are similar for both categories.

Table 93.5. Comparing the Trickle Migration strategy with the Replatforming technique using a T-test with a 95% confidence interval. 0.009 is the significance value (p < 0.05). It is obvious that these groups differ statistically significantly from one another

Efficiency	Levene's Test for Equality of Variance		T-test for Equality of Means					95% Confidence of Interval of the Difference	
	F	Sig	t	df	Sg. (2-tailed)	Mean Difference	Std. Error Difference	Lower	Upper
Equal variance assumed	.602	.448	2.906	18	.009	7.500	2.580	2.078	12.92
Equal variance not assumed			2.906	16.54	.009	7.500	2.580	2.043	12.95

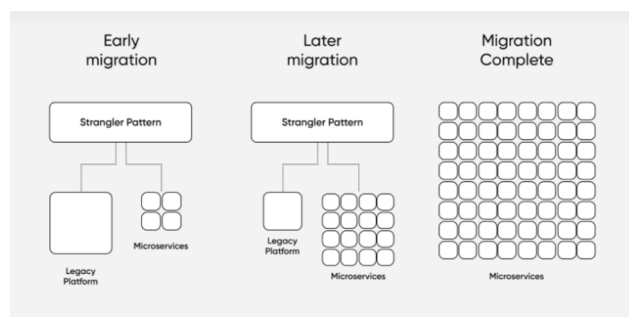
Source: Author.


Figure 93.1. Working process of database replatforming.

Source: Author.
Figure 93.2. Replatforming techinique graph.

Source: Author.

The results indicate statistically significant differences between the groups, with a p-value of 0.009, which is less than the alpha level of 0. To compare the effectiveness of the Trickle Migration strategy with the Replatforming technique, a graph was created and is shown in Figure 93.2.

6. Discussion

In this Experimental analysis, we observed that the Trickle Migration approach is better than the Replatforming technique in all aspects. The trickle approach runs in both old and new systems in parallel where the Replatforming technique can be completely started over to different locations. The resource intensive and much more complex compared to lift-and-shift migration. It requires advanced coding, automation, and DevOps replatforming, requiring changes to many aspects of the application and increasing the risk of failure at the code, configuration, and infrastructure levels. The aggressive changes lead to minimising the work which leads to sticking to the common well known cloud components. The same study report [7] on improving database migration in cloud settings came to the same conclusion that trickle migration is the best method for carrying out database migration. According to this study on Dynamic migration in cloud databases states that 65% improvement is achieved in terms of query response time. The successful migration of legacy patent data to the cloud. The opposing finding and states that the Replatforming technique ensures an over-time reduction in costs, matching the resource compensation which the demand and eliminating the residue. There are several problems that must be addressed in order to accomplish and develop the migrations of data, a disjointed database architecture, prolonged downtime, the possibility for data loss, more expense, and inherited low data quality.

7. Conclusion

The best method for moving your database or application is shown in the research, along with the procedure for organising and carrying out these migrations, using the Azure Database Migration Service (DMS).

The Trickle migration approach performs better than Replatforming (84.46%).

94 Design and comparison of RF analyses of an innovative SSE structure microstrip aerial using FR4 and arlon AD300A materials for S-band applications

Prakash L. and Anitha G.[a]

Electronics and Communication Engineering (ECE) Department, Saveetha School of Engineering (SSE), Saveetha Institute of Medical and Technical Sciences (SIMATS), Chennai, India

Abstract: To design and compare a innovative SSE-structure microstrip aerial (combination of S-structured and E-structured radio wire) using FR4 fabric and Arlon AD300A fabric for 3.6 GHz S-band applications. Materials and methods: The RF analyses of the two materials was investigated by evaluating parameters such as return loss, and VSWR. Each fabric test score was 27 for a test measurement of 54. Result: The RF analyses of the FR4 fabric was found to dominate the RF analyses of the Arlo AD300A fabric, with the FR4 fabric achieving the next analyses loss. (−30.240 dB vs. −29.79 dB), lower VSWR (0.5345 vs. 0.761351), lower gain (−0.33 dB vs. 5.50 dB), and lower impedance (52.28 Ω vs. on frequency 7 GH55.8). The mounting dimensions of both materials are 38.03 mm x 29.28 mm. Actual research showed a critical difference between the two materials, p being 0.001 and 0.001 (p<0.05).

Keywords: Innovative SSE structure aerial, FR4, return loss, voltage standing wave ratio, aerial design, RF analyses, communication technology

1. Introduction

The purpose of this paper is to compare the RF presentation of an innovative SSE-structured microstrip aerial operating at 3.6 GHz using FR4 and Arlon AD300A substrate materials. RF analyses characteristics calculating return loss, and VSWR are evaluated and compared between the two materials. Integrating the radio wire into the printed circuit design can improve the impedance coordination of the radio wire and promote RF chain integration as part of the follow-up to the Communication Innovation Framework [1]. Patch beam wire can be a type of beam wire made by carving a pattern into a conductive fabric on a dielectric surface, usually a PCB. The ground plate, which acts as a base for the radio cable, is made of dielectric fabric. Microstrip aerials are often used in remote communication innovation frameworks because they can be easily coordinated with the PCB plan and can provide high impedance coordination through the RF circuit [2]. Microstrip chips are common due to their small size, weight, motion detection, comfort of fabrication, accessibility with coordinate chains, and comfort of incorporation with supplementary systems. Due to their interesting purposes, they have been widely used in many applications [3]. Microstrip chips have a widespread array of tenders in various fields, including space communication innovations, phased array receives line applications [4], mobile communications for ESA applications, remote communications [5] and portable applications. Circular Microstrip Patch Probe Design for X-Band Claims [6] investigates the proposal and analyses of a pi-slotted quadrilateral microstrip probe for use in 5G communication innovation frameworks.

2. Related Study

Various requests for papers on microstrip patch aerial have been circulated over the past five years. IEEE Investigate has 35 articles and Google Researcher has 2400 articles. A square microstrip radio conductor is placed and replicated on a half-array consisting of a Rogers TMM4 substratum with a ferrite loop. This design is associated to a four-sided microstrip patch aerial on a typical Rogers TMM4 substratum without a ferrite ring. The generation of these excitations is compared to determine the effect of the ferrite ring on the RF efficiency of the chip aerial [7]. The proposed microstrip patch aerial designed to operate at 5.8 GHz is acceptable for far-field array applications [8]. This study presents the design of an open-coupled lossy silicon substrate patch aerial. A radio wire with a 15 GHz aperture and a transmission silicon conductor was developed and tested. The starting point for the measured and calculated analyses losses are the reverberation frequencies of 14.7 and 14.8 GHz and the transmission speeds of 0.7 and 1 GHz separately. The simulated radiation patterns appeared high in the front to increase the ray line fraction [9]. A microstrip chip aerial was designed on an EBG (Electromagnetic Bandwidth) substrate and its broadband analyses was tested. The results showed that the use of a two-layer EBG substrate made it possible to create a broadband radio wire with an impedance transmission power of 24.69% and a gain-gain of more than 3 dBi compared to the reference aerial.

Preliminary investigations are needed to compare the presentation of the innovative SSE-structured microstrip chip aerial using different substrate materials. It examines the RF analyses of a original SSE structured microstrip probe at 3.6 GHz using FR4 and Arlon AD300A materials. RF analyses parameters calculating return loss, and VSWR were evaluated using the HFSS program. The result of this consideration shows the suitability of these materials for use in SSE-structured microstrip aerial designs for S-band applications.

3. Methodology

It compared the RF analyses of an innovative SSE structured microstrip patch aerial utilizing FR4 and Arlon AD300A materials. Each gather had a test estimate of 27, coming about in a add up to test estimate of 54. The pre-test was conducted with an alpha esteem of 0.05 and decided that 80% of the test ought to be utilized for testing.

The primary step in this ponder was to plan and recreate a innovative SSE formed microstrip patch aerial utilizing the FR4 fabric at a frequency of 3.6 GHz utilizing the ANSOFT HFSS computer program. The ground plane and substrate measurements were made utilizing the measurements indicated in Table 94.1. The patch was made employing a empty 2.5 mm wide rectangle, with the letters SSE carved interior utilizing rectangles with the measurements indicated in Table 94.1. The excitation and investigation framework were set up and the design was approved some time recently being run to get the specified comes about of return loss, and VSWR.

This considers points to plan and analyze the RF analyses of an innovative SSE formed microstrip patch aerial utilizing FR4 substrate fabric. The measurements of the receiving wire structure are 50 X 49.5 X 2 mm³, and the fix measurements are 38.03 X 29.28 mm². The fix is associated to the source, and both the fix and the ground plane are associated to the source. The design of the patch is displayed in Figure 94.1 and the measurements, for the base, ground plane and substrate can be found in Table 94.1.

ANSOFT HFSS program was used to analyze the RF analyses of the new SSE-structured microstrip aerial fabricated from Arlon AD300A fabric at 3.6 GHz. The method started with opening the HFSS program and doing a modern format. The base plate and substrate were fabricated in this step using the measurements shown in Table 94.2. A rectangular shape, with a width of 2.5 mm was sketched as the foundation and within that rectangle the letters SSE were created using rectangles, with measurements mentioned in Table 94.1. Based on the measured measurements, the boundaries were defined and the setting and research framework was organized. The design was accepted and run to obtain the specified analyses by calculating the return loss, and VSWR.

Table 94.1. Dimensions of a Innovative SSE Structured Microstrip Patch Aerial with FR4 and Arlon AD300A Substrates at 3.6 GHz

Parameters	Group-1 Values	Group-2 Values
Resonance frequency	3.6 GHz	3.6 GHz
Substrate	FR4	Arlon AD300A
Dielectric constant	4.4	3.0
Substrate height	2 mm	2 mm
Patch width (W_p)	38.03 mm	38.03 mm
Patch length (L_p)	29.28 mm	29.28 mm
substratum length (L_{sub})	50 mm	50 mm
Substrate width (W_{sub})	49.5 mm	49.5 mm
Length of ground plane (L_g)	50 mm	50 mm
Width of the ground plane (W_g)	49.5 mm	49.5 mm

4. Statistical Analysis

For statistical analysis of the data, the data are translated into Excel and then entered into the SPSS program. The independent samples t-test was used as part of the statistical approach in this study. Because they do not change when other variables are adjusted throughout the experiment, wavelength and dielectric thickness are the only factors taken into account individually in this investigation. Chip length, chip location, and impedance matching are dependent factors that were studied because they are affected by changes in the independent variables.

5. Results

The RF analyses of the new SSE-structured patch aerial using FR4 and Arlon AD300A substratum materials was analyzed at 3.6 GHz using the HFSS computer program. To optimized values for return loss, and VSWR emerged for both materials.

Table 94.2 appears to be of an innovative SSE-structured patch aerial with substrates made of FR4 and Arlon AD300A at 3.6 GHz. The RF analyses of FR4 and Arlon AD300A substrates is significantly versatile, with a p-value of less than 0.05 for example. Also, the unpaired t-test appears to be a critical difference between the two packages, with a p of 0.001 and 0.001 ($P < 0.05$) for both analyses loss and VSWR. The RF analyses of the proposed FR4 substrate design with other materials and the proposed design appears to have a lower VSWR of 0.5345, forward return loss of -30.240 and impedance of 52.28 Ω at 3.6 GHz.

RF analyses of FR4 fabric when calculated for return loss (-30.2407 dB), VSWR (0.5345), impedance (52.28 Ω) and gain (-0.33 dBi). RF analyses of a microstrip plate aerial calculating return loss (-29.79 dB), VSWR (0.7613), impedance matching (55.87 Ω) and gain (5.50 dBi). The RF analyses of FR4 and Arlon AD300A materials is compared in Figures 94.2 and 94.3 separately for FR4 return loss and VSWR.

The FR4 has a return loss of -30.240 dB, while the Arlon AD300A has a return loss of –29.79 dB. The VSWR of the FR4 is 0.5345, while the VSWR of the Arlo AD300A is 0.7613. The RF analyses of the FR4 fabric was compared with the Arlo AD300A fabric using the bar graph shown in Figure 94.4. The graph showed that the analyses loss of the FR4 fabric was as follows and the raw VSWR was slightly higher than the Arlo AD300A fabric. The x-axis is for the FR4 and Arlon AD300A arrays, while the y-axis shows the raw return loss and raw VSWR of each array, with a position run of +/-1 standard deviation. The RF analyses of FR4 and Arlon AD300A materials was compared with parameters. It turned out that the FR4 had better brutal return loss and a slightly higher brutal VSWR than Arlon's AD300A. In terms of RF analyses, the FR4 was found to dominate the Arlo AD300A.

6. Discussion

The RF analyses of the new SSE-structured patch aerial was compared using FR4 and Arlon AD300A as substrate materials at 3.6 GHz. The paremetes of the rectangular microstrip mount were evaluated and it was found that the analyses of the FR4 substrate was much better than that of the Arlon AD300A substrate.

Figure 94.4. FR4 and Arlon AD300A RF demonstrations are compared on a bar graph in terms of (a) return loss and (b) VSWR. (Blue bar - moo return loss and insignificant VSWR in Arlon AD300A; ruddy bar - tall return loss in FR4). Arlon AD300A appears to have inferior RF

Table 94.2. Dimensions of an Innovative SSE Structured Microstrip Patch Aerial with FR4 and Arlon AD300A Substrate at 3.6 GHz

Substrate Materials	Return Loss (dB)	VSWR	Gain (dBi)	Impedance (Ω)
FR4	–30.240	0.5345	–0.33	52.28
Arlon AD300A	–29.79 dB	0.7613	5.50	55.87

Source: Author.
Figure 94.2. Comparison Return loss analyses of FR4 and Arlon AD300A.

analysis compared to FR4. Cruel Return loss and Cruel VSWR of FR4 and Arlon AD300A of Discovery +/-1 SD are the Y Hub and X pivot, respectively. The RF loss analyses is –24.315 dB, VSWR is –1.26, and impedance is –46.98 at 2.4 GHz, which is consistent with previous studies [10]. The RF efficiency of the chassis at 2 GHz was measured to be –18 dB and VSWR 1.65 [11]. At 4.5 GHz, the patch aerial consumes a return loss of –17.2 dB and a VSWR of 1.3 [12]. The proposed patch aerial design appeared to improve analyses in terms of return loss (–30.240 dB) and VSWR (0.5345) at 3.6 GHz compared to previous designs at lower frequencies.

Various variables can affect the RF analyses of a patch aerial, such as the fabric of the substrate. The proposed new SSE-structured patch aerial design had a return loss of -30.240, a VSWR of 0.5345, and an impedance of 52.28 at 3.6 GHz, which is much better than other designs. Be that as it may, the acceleration of this receiving wire is less than desirable. In the future, this radio thread can be taken out by leaps and bounds by combining additional materials with a plan for S-band applications.

7. Conclusion

This paper investigates the RF analyses of a new SSE-structured microstrip aerial consuming FR4 and Arlon AD300A substrate materials at 3.6 GHz. The FR4 fabric appears to offer better RF analyses compared to

Arlon's AD300A fabric and is reasonable for a variability of S-Band applications.

95 Detecting the accurate moving objects in indoor stadium using you only look once algorithm compared with ResNet50

Shaik Khasim Saida[a] and V. Parthipan

Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The aim of this study is to use You Only Look Once to follow players and their movements across indoor stadiums, and to compare the results with ResNet 50 to enhance accuracy. This study is divided into two groups: You Only Look Once and ResNet 50. Sample size is 10 for each group, calculated using ClinCalc software with a 95% confidence interval and a 0.05 alpha value. The motion detection dataset with a size of 1500 images was considered from Kaggle.com. It was discovered that the proposed method achieved 95.680% accuracy when compared to the current system, which only had an accuracy of 93.270%. Evaluating independent sample T-test, it was proved that YOLO was much more accurate than and SMD models, with a statistical difference between the value of p=0.000 (Independent sample t-test p<0.05). The You Only Look Once method is noticeably superior to the ResNet50 algorithm at detecting moving objects in indoor stadiums according to experimental results.

Keywords: Novel object detection, ResNet50, roads, tensorflow, transport, vehicles, you only look once, YOLO

1. Introduction

Utilizing computer vision techniques to identify and tag things in a video stream is known as "novel object detection." [2]. Following moving targets or objects in real-time video with Tensorflow is an important and difficult challenge. Even though numerous techniques have been used to date to find mechanisms [10]. YOLO is able to identify transport vehicles on the roads using the image it has collected. One of them is the deep neural network, which elaborates the hidden layers to noticeably improve novel object detection in videos. [14]. A deep convolutional neural network, which was initially employed as the detection mechanism, forms the foundation of R-CNN in 2014 [4]. Later, new, improved techniques including Spp-net, quick R-CNN, quick RCNN, and R-FCN were added to the API. Due to their intricate network architecture built using TensorFlow, they are not ideal for use in

distinguishing numerous real-time objects in a single frame [13].

This subject has been covered extensively in literature during the last few years. A significant number of publications have been made over the preceding five years, including over 16500 papers in Google Scholar and 54 IEEE journals in image processing and were retrieved based on their research theme. The analysis of aerial movies shot by flying machines has gained importance in recent years [3, 18] is cited 54 times. Three sub modules make up the Moving novel Object Detection module. One of the most reliable real-time background subtraction models to be discovered in literature is the one used in the thesis of tensorflow. To create the first background model, this background subtraction model first uses a pixel-wise median filter over time (20–40 seconds) to distinguish between moving and stationary pixels [17] is cited 54 times. As a result, aerial surveillance systems make a fantastic addition to ground-based surveillance systems [7, 8]. Scene registration

and alignment is one of the key areas of discussion in aerial picture analysis [6, 15, 16]. Using the image captured, YOLO can detect Transport vehicles on the Roads. Vehicle recognition and tracking is another crucial aspect of intelligent aerial surveillance. Aerial surveillance poses difficulties for vehicle detection due to camera movements such panning, tilting, and rotation. Target item sizes also vary as a function of the height of aerial platforms [7].

According to the research gap, it was determined that the previous work is insufficiently accurate to detect moving objects. This study aims to increase perceived accuracy by using You Only Look Once over ResNet 50.

2. Materials and Methods

This paper discusses the improvement of the ResNet 50 classifier and the You Only Look Once Model using four machine learning techniques. The mean and standard deviation used to determine sample size 10 were obtained from earlier studies. Each group has a sample size of 10 and two groups to implement the suggested techniques. G-power 80%, alpha 0.05, and beta 0.2 are used in the calculation, and a 95% confidence interval is used. The experiment included two groups of algorithms: Group 1 used the You Only Look Once algorithm, while Group 2 used the ResNet50 algorithm [20] (https://clincalc.com/stats/samplesize.aspx).

The testing environment consists of a Matlab IDE, SPSS version 26.0.1, and a laptop with 8 GB RAM, Intel 10th generation i5 processor, and a 2 GB graphics card. The dataset is shrunk via slicing with the object detection dataset with a size of 1500 images was considered from Kaggle.com. [12], then it is examined and put to the test using environment-specific Matlab.

3. You Only Look Once (YOLO)

Novel Object Detection, a subfield of computer science associated with computer vision and image processing, focuses on finding instances of semantic objects of a particular class (such as people, buildings, or cars) in digital images and videos. Two well-researched novel object identification fields are face and pedestrian detection. Novel Object Detection is used in several computer vision fields, including image retrieval and video surveillance. YOLO is able to identify transport vehicles on the roads using the image it has collected.

YOLO, a revolutionary approach to object detection, is presented. In the past, classifiers have been employed for novel object detection. We now think of new item detection as a regression problem to spatially varied bounding boxes and related class probabilities. A single neural network can directly predict bounding boxes and class probabilities from whole photos in one

assessment. The detection performance may be modified from start to finish because the entire detection pipeline is made up of a single network. YOLO is able to identify transport vehicles on the roads using the image it has collected. Our seamless architecture is extremely speedy. Our core YOLO model processes photos in real time at a frame rate of 45 frames per second. Fast YOLO, a scaled-down version of the network, processes just 155 frames per second while still outperforming other real-time detectors in map by a factor of two.

3.1. Procedure

Step 1: Create a function to filter the boxes based on thresholds and likelihood after importing the necessary photos.

Step2: Make a function that calculates the AOI.

Step3: Create a Non-Max Suppression function.

Step4: After using the shape to generate a random volume, predict the bounding boxes. (18,18,4,84).

Step5: Construct a way to foresee the bounding boxes, then save the images with these bounding boxes in place.

Step6: Make predictions after reading an image with the forecast tool.

Step7: Yolo eval can be used to predict a random volume.

Step8: Utilize the threshold algorithm to convert the preprocessed image to a binary image.

Step 9: Segment each unique Object that is visible in the picture.

Step 10: Using the average values of the geometric characteristics' major axis, minor axis, and area, do a quality analysis on each unique object.

3.2. ResNet50

Microsoft Research unveiled ResNet-50, a deep convolutional neural network architecture, in 2015. It is a variant of the ResNet family of models that was designed to address the vanishing gradient problem that arises when training very deep neural networks. The ResNet-50 architecture consists of 50 layers and is composed of several residual blocks, each containing multiple convolutional layers. The main innovation in ResNet-50 is the use of skip connections or shortcut connections, which allow the gradient to flow directly from the input of a residual block to its output, bypassing the intermediate layers. These skip connections help to alleviate the vanishing gradient problem by allowing the gradients to flow more easily through the network, which leads to faster convergence during training and better performance on various image segment tasks.

ResNet-50 has been widely used as a pre-trained model for transfer learning in a variety of computer vision applications, including object detection, image segmentation, and image segment. It achieved

state-of-the-art performance on the ImageNet dataset, which is a large-scale benchmark for image segments. While ResNet-50 has achieved impressive performance on various image segment tasks, it may not generalize well to other domains or tasks. It is important to consider fine-tuning or adapting the model to the specific task at hand. Due to its large size, ResNet-50 is prone to overfitting, especially when the training data is limited. Regularization techniques such as dropout and weight decay can help alleviate this problem. ResNet-50 has a large number of parameters and is computationally expensive to train, making it challenging for researchers with limited computational resources to use.

3.3. Procedure for ResNet50

Step 1: First, we import the keras module and its APIs. These APIs help in building the architecture of the ResNet model.

Step 2: Now, We set different hyper parameters that are required for ResNet architecture. We also did some preprocessing on our dataset to prepare it for training.

Step 3: In this step, we set the learning rate according to the number of epochs. As the number of epochs increases, the learning rate must be decreased to ensure better learning.

Step 4: Define a basic ResNet building block that can be used for defining the ResNet V1 and V2 architecture.

Step 4: Define ResNet V1 architecture that is based on the ResNet building block we defined above.

Step 5: Define ResNet V2 architecture that is based on the ResNet building block we defined above.

Step 6: The code main function is used to train and test the ResNet v1 and v2 architecture we defined above.

4. Statistical Analysis

The statistical comparison of the suggested and compared algorithms is done using the IBM SPSS 26.0.1 application. The dataset's dependent variables are the scales and item columns. The independent variables in the dataset are store, date, and item. The independent sample T-test analysis used both the method compared and suggested. These algorithms' object identification accuracy will show that the You Only Look Once (YOLO) Model outperforms the ResNet 50 model with higher accuracy [11].

6. Results

The group statistics results perform on all variables. It is clearly seen that improved YOLO obtains best accuracy and standard deviation when compared to ResNet 50 using Independent sample t-test results.
Figure 95.2. Compares the accuracies of You Only Look Once model and ResNet 50 model using the linear graph representation.

Source: Author.

The importance of equality variance, which indicates that the study work's findings are substantial and correlated with one another, accounts for the discrepancy in accuracy between YOLO and ResNet 50. The accuracy comparison of YOLO and ResNet 50 algorithms shows the You Only Look Once algorithm outperforms the ResNet 50 algorithm.

Table 95.1 displays the outcomes of implementing the You Only Look Once model and ResNet 50 model to detect moving objects in the stadium. The values predicted by the graph are stated as statistical data, and each model had 10 data samples.

Source: Author.

Table 95.2 demonstrates the mean accuracy differences between ResNet 50 and the You Only Look Once model, revealing that ResNet 50 has a greater accuracy than the You Only Look Once model (93.280% vs. 93.280%).

Table 95.3 demonstrates the group statistical findings for all iteration variables. The You Only Look Once Model has outperformed the ResNet 50 Model in terms of performance. The ResNet 50 Model's mean accuracy is 93.270%, compared to the You Only Look Once Model's mean accuracy of 95.680%. The standard deviation of the Resnet 50 model is 0.3268, while that of the You Only Look Once model is 0.2150. The standard error mean for the ResNet 50 Model is 0.1033, compared to 0.0680 for the You Only Look Once model.

Table 95.4 results of the independent sample T test are shown. The independent sample T test for equality revealed that the ResNet 50 Model and the You Only Look Once Model in this study had comparable mean differences of 2.4100 and standard deviation differences. The 95% confidence interval for the ResNet 50 Model was 2.6728. With p=0.000 (Independent sample t-test p<0.05), there is a statistically significant difference between the ResNet50 model

and the YOLO Model. The new You Only Look Once Model is favored as a result of the significant variance difference.

Figure 95.1 shows the flow data processing and use case model for the You Only Look Once (YOLO) algorithm.

Figure 95.2 compares the accuracies of You Only Look Once model and ResNet 50 model using the linear graph representation.

Figure 95.3 compares the Sensitivity of You Only Look Once model and ResNet 50 model using the linear graph representation. Figure 95.4 compares the You Only Look Once Model's accuracy to that of the ResNet 50 Model using the bar graph representation using the programme The IBM SPSS 26.0.1. The Shot Multibox Detector Model is significantly outperformed by the new You Only Look Once Model.

7. Discussion

In the research work, it is observed that You Only Look Once (YOLO) model outcomes with an accuracy of 95.680% whereas existing ResNet 50 with 93.270%. When compared to the ResNet 50, the You Only Look Once model is more accurate for using the You Only Look Once and ResNet50 Model, an efficient analysis of moving novel Object Detection in the indoor stadium is performed.

The proposed model is to build a machine learning model that is capable of identifying the moving object's images accurately [9]. It can be easy to capture the image of an object when it is stable at the single place but it is tough to predict the image when it is moving [5]. So there is a greater chance for the people or when it comes to games it is tough to identify the players in the field by the referee when the players are in moving condition. Machine learning is generally built to tackle these types of complicated tasks [1]. It takes more time to analyze these types of data manually by humans [19]. Machine learning can be used to identify if the object's position was stable or not by using the previous data and making them understand the pattern and improve the accuracy of the model by adjusting parameters and using that model as the segment model [11]. Different algorithms can be compared and the best model can be used for segment purposes.

A few restrictions apply to this study even though the proposed You Only Look Once (YOLO) model outperformed the current approach. The system can only forecast an object based on its appearance in a picture, it is unable to track a moving object using sound. Future cloud deployments of this project are possible. Additionally, more data can be used to do this [21].

8. Conclusion

This research is done to detect the moving object by using the You Only Look Once to enhance the accuracy and compare with the Resnet 50 algorithm. As a result, it shows that the You Only Look Once model (95.68%) is better than the ResNet 50 Model (93.27%) for the detection of the moving object.

[3]Research Associate, Department of ECE, Saveetha School of Engineering, SIMATS, Chennai, Tamilnadu, India

Abstract: This investigation centers on the novel deduction of cyberbullying via the use of recurrent neural networks, as well as the comparison of the accuracy of such deduction to that of an adaptive boosting classifier. This strategy utilizes two distinct groups in its implementation. Group 1, on the other hand, was graded with the help of recurrent neural networks, while Group 2, on the other hand, was graded using the Ada Boost algorithm. Each of the two groups received a total of twenty instances to analyze in order to judge how accurate the unique deduction of cyberbullying was. The size of the sample was calculated using the G power statistic, and the threshold for significance in the pretest was established at 80%. In compared to the accuracy achieved by the Ada boost (93.3%), the accuracy achieved by the RNN is much improved, coming in at 94.7% with a statistical significance of 0.18 (p>0.05). The Ada boost classifier has a lower accuracy than the Recurrent Neural Network approach, which has a substantially greater accuracy.

Keywords: Recurrent neural network (RNN), cyberbullying, novel deduction, adaptive boost (Ada boost), accuracy

1. Introduction

When referring to a kind of bullying or harassment that takes place via the use of the internet, one may talk about cyberbullying or cyberharassment. There has been an increase in the use of technology, particularly among younger generations, as a result of the expansion and dissemination of the digital world. Examples of damaging activities that may be categorized as bullying include the propagation of rumors, the making of comments that are threatening or sexual, the disclosure of personal information about a victim, and the labeling of the victim with terms that are disparaging. A recurrent neural network, often known as an RNN, is a kind of artificial neural network that, over the course of time, the connections between the nodes construct either a directed or an undirected graph [1]. As a consequence of this, it is able to carry out operations in a way that is responsive to the passage of time. RNNs, which are built from feedforward neural networks, have the ability to process input sequences of varying lengths by making use of the state information that is kept inside themselves. As a direct consequence of this, activities that were thought to be impossible in the past, such as identifying continuous and linked handwriting or continuous speech, are now within reach. In a recurrent neural network, or RNN for short, the output of one stage serves as the input for the stage that comes after it. Because of the many negative effects that it

has on people, cyberbullying has been a major source of concern in recent years. According to studies on the psychological well-being of teens, cyberbullying [5] is also a risk.

2. Materials and Methods

The Image Processing Laboratory in the Saveetha School of Engineering is where the study is being conducted at the moment. RNN and AdaBoost are the primary tools utilized in the production of samples for groups 1 and 2. RNNs are a kind of neural network that can be used to model sequences, which makes them suitable for analyzing text data such as the posts, comments, and messages that are seen on social media platforms, which is where the majority of instances of cyberbullying occur. The following provides an outline of how RNNs may be used for the automated identification of cyberbullying: It is recommended that a labeled text data collection consisting of occurrences of cyberbullying and material that is not considered cyberbullying be acquired. The text data was subjected to preprocessing, which consisted of a variety of procedures such as tokenization, lowercasing, the removal of special characters, and stopword removal. In order for the preprocessed text input to be used with the RNN, numerical vectors need to be created from the text. When evaluating the performance of the model on the testing dataset, it is helpful to make use of performance measures such as accuracy, precision, recall, F1-score, and AUC-ROC. Iterating on the model's design and hyperparameter settings may help improve the performance of the model. In order to cope with false positives and false negatives, the outputs of the model should be post-processed as appropriate. For example, by using rule-based filters, you may be able to increase the accuracy of the predictions.

2.1. Statistical analysis

The statistical analysis was carried out with the help of the application IBM SPSS. A T test based on an independent sample was carried out. Regarding the RNN and Ada Algorithms for the purpose of data analysis. Twenty samples were generated for both the proposed and the current algorithms, and for each sample, the projected accuracy was documented for subsequent examination in the Microsoft Excel sheet that was provided by the SPSS programme.

Accuracy serves as the dependent variable, while the independent variables are the many areas of the country, each of which has a unique virus strain necessitating the collection of a separate dataset [16].

3. Result and Discussion

Table 96.1. Percentage of accuracy acquired between RNN and Ada boost of 20 samples each with a mean accuracy of 94.7 for RNN and 93.3 for Ada boost

Samples	RNN	Ada boost
1	95.50	92.11
2	95.12	92.35
3	95.35	92.05
4	94.13	92.66
5	94.65	92.50
6	94.82	93.37
7	94.60	93.34
8	94.32	93.03
9	94.59	93.56
10	94.66	93.15
11	95.09	93.94
12	94.71	93.37
13	94.74	92.56
14	94.37	92.25
15	94.67	93.18
16	94.62	93.50
17	94.11	92.71
18	94.35	92.65

proposed for dataset classification. The study uses state-of-the-art RNN architectures in Figure 96.1 for automatic deduction of cyberbullying. Transfer Learning achieved a promising 95.5% accuracy in deduction of cyberbullying in this study. In another paper the study was performed on the validation and adaptability of deep decomposition, transfer and composition RNN for the deduction of cyberbullying [7] using adaboost classification [8] by the researchers reported the

study results with an accuracy of 95.12% in prediction of coronavirus. In this research the author has provided a methodology for the prediction of the presence of the novel on deduction of cyberbullying through a proposed cyberbullying model [9]. The prediction accuracy of the proposed method is 89.7%. However, in this area, precision is really high. As a result, no other remarks are wrongly classified as threats. Low recall indicates that it is unable to successfully recognise all threat remarks due to a lack of training data in the 'threat' category [10]. It can be enhanced in the future if the training set is given more data. In another research done with different RNN based deep learning networks were used to identify the better deep learning technique in terms of extracting the various deductions of cyberbullying. The highest accuracy obtained in RNN based model is 95.5%.

Processing a huge dataset creates a computational complexity in the proposed work. In future, the proposed work will be improved by having less computational time compared to the existing algorithm.

4. Conclusion

From this analysis, it is clear that, Novel deduction of cyberbullying using Recurrent Neural Network produces higher accuracy of 95.50% when compared to the Ada boost algorithm.

97 Prediction of share market stock price using long short-term memory and compare accuracy with Gaussian algorithm

K. Sanath Reddy[a] and G. Ramkumar

Department of ECE, Saveetha School of Engineering, SIMATS, Chennai, Tamilnadu, India

Abstract: This article's main goal is to demonstrate how Novel Long Short-Term Memory (LSTM) can forecast stock prices more accurately and precisely than the Gaussian Algorithm. This research used the publicly available dataset given by the National Stock Exchange (NSE) to show the effectiveness of the technique. Using G-power 0.8, a 95% confidence interval, and alpha and beta values of 0.05 and 0.2, respectively, predictions of the share price were created. The sample size distribution was as follows: alpha = 0.05, beta = 0.2. The total sample size was 280 (Group 1 = 140 and Group 2 = 140). Our stock market price projections are more precise and accurate because we combine the Gaussian Algorithm with a special Long Short-Term Memory and a large number of samples (N=10). The Novel Long Short-Term Memory classifier is 93.94% more accurate than the Gaussian Algorithm, whose accuracy rate is substantially lower at 74.88%. It was concluded that the research's findings were statistically significant at the level of 0.05, or p=0.0271. Novel Long Short-Term Memory outperforms the Gaussian Algorithm in terms of stock price prediction. This is due to the complexity of the Gaussian Algorithm.

Keywords: Novel long short-term memory, Gaussian algorithm, accuracy, stock price, precision, machine learning techniques, stock price prediction, stock market

1. Introduction

A strategy that is used often in the academic world as well as the business world is one that attempts to forecast the values that stock indexes will have in the foreseeable future. This study is being carried out with the purpose of building a state-of-the-art machine learning system with the potential of making accurate forecasts regarding the movement of stock prices [3]. The major purpose is to arrive at a prediction of the index price for the next trading day that is as exact and precise as is possible. The results of the tests indicate that the Novel Long-Short-Term Memory performs more effectively than the models that it is competing with, which is proof of the utility of the technology. The findings of this research imply that the historical value of an asset is not influenced by other happenings that take place in the market, and that it is possible to create accurate forecasts of future movement by utilizing this value. This conclusion was reached as a consequence of the fact that the value of the asset did not change during the course of the study. This is the case regardless of the fact that the model suffers from a variety of other flaws. In spite of the fact that there are a number of other problems with the model, this remains the case. One of the most significant drawbacks of these methods is that they take this approach. In this sense, these procedures are plagued by one of the most significant flaws there is to be found.

2. Materials and Methods

When it comes to the world of finance, deep learning is often used in the form of a Long Short-Term Memory neural network to generate predictions on the value of stocks. Modeling sequences and time

series data, such as stock price data, is a task that lends itself particularly well to the use of recurrent neural networks of the LSTM type. A dataset must include the relevant components, which include the date, the open price, the high price, the low price, the closing price, and the transaction volume. For purposes of training, it is customary to make use of the earlier portion of the data, while the more recent part of the data is put to use for testing. It is common practice to do so in an effort to improve the efficiency of the training process. The capability of the model to recognize links and patterns in the historical data relating to stock prices will be improved as a result of this work. Compare the projected stock prices to the actual prices of the stocks in order to evaluate the accuracy of the model as well as its ability to spot trends and patterns. In general, it pertains to the process of gathering the appropriate dataset. The data were preprocessed in order to get a higher degree of accuracy in the predictions. Feeding the data to the algorithm in order to refine the test data is analogous to the process of training the machine.

3. Results and Discussion

Figure 97.1 shows the simple Bar graph for Novel Long Short-Term Memory accuracy rate is compared

with Gaussian. The LSTM is higher in terms of accuracy rate 93.94 when compared with Gaussian 74.88. Table 97.1 illustrates the comparison between LSTM and GA. Tables 97.2 and 97.3 shows the statistical calculation analysis respectively.

According to the results of this study, the accuracy of predicting stock prices using the Novel Long Short-Term Memory algorithm is greater than that using the Gaussian algorithm. This is the conclusion drawn from comparing the two algorithms' predictive capabilities. A comparison was carried out between LSTM and Gaussian using the same training set data and test set data in the same operating environment. This was done since LSTM is more accurate than Gaussian. This was done so that the usefulness of novel long-term short-term memory may be highlighted.

Researchers from a wide variety of academic fields are investigating the viability of using deep learning algorithms to properly forecast movements in the stock market [9]. This study will investigate various different approaches to forecasting the pricing of stocks for the next trading day. When determining the order in which Thai stock indexes are ranked, the Stock Exchange of Thailand 50 (SET50) index is one of the factors that

is taken into account. Throughout the course of this inquiry, a Recurrent Neural Network (RNN) equipped with Long-Short Term Memory (LSTM) is being used. Jeff Elman was the one who first proposed the idea of a Recurrent Neural Network, often known as an RNN. A recurrent neural network, often known as an RNN, is a kind of deep neural network that is capable of processing consecutive input. RNNs are built on the notion that the sequential information they use as their basis is the key to their success. RNNs, or recurrent neural networks, get their name from the fact that they perform the same task for each element in a sequence, with the result being dependent on the computations that came before [10]. This is why recurrent neural networks are also known as RNNs. The objective of stock prediction is to first extract relevant characteristics from previously amassed data and then to devise an estimate of the price change trend that will take place in the upcoming periods of time. The capacity of RNN to do sequential data processing is what makes it feasible for it to achieve this goal. It is a widely held belief that the individual components of a basic neural network are capable of functioning independently. The only thing that may influence the outcome of the prediction is the input variable that corresponds to it. On the other hand, RNN has the ability to recall prior outputs that it has created for itself. In other words, the output at time t, which is marked by St and affected not only by the input at that time, which is denoted by Xt, but also by the result of the step that occurred before it, which is depicted by St-1, is influenced. The traditional RNN has a few flaws, the most serious of which is the fact that the gradient may sometimes disappear. When the data series is extremely long, the gradient will quickly go closer and closer to zero [11], but it will not remain at that value. In this work, we show that despite the fact that mistakes in prediction are unavoidable due to the inadequacy of the model and the unexpected behaviors of the market, both

optimization prediction approaches perform reasonably well in terms of generating long-term stock price forecasts. This is the case despite the fact that errors in prediction are inevitable owing to the inadequacy of the model and the unpredictable behaviors of the market. Additional modifications to the model, such as leveraging the weights across predictions and decreasing cumulative error, may be implemented for future research and application, which will result in more consistent accuracy [12]. These additional upgrades may include the following: leveraging the weights across predictions; lowering cumulative error. These improvements are feasible to put into action.

One may guess on what the price will be at the conclusion of the following trading day by looking at the beginning price and change from the previous trading day. After the raw data have been pre-processed in the appropriate way, the essential components required for the development of predictive models are found. The prediction framework was further enhanced by incorporating LSTM models using univariate and multivariate methodologies, altering the quantity of the input data, and configuring the network in a number of different ways. This was done after building and testing models based on machine learning and deep learning. It was discovered that the performance of these deep learning models based on LSTM was significantly superior than that of the Gaussian model (74,88%). These models were able to obtain an accuracy rate of 93.94 percent overall. The main limitation of LSTM is that it might be difficult to choose an appropriate model that is both capable of rapid learning and accurate representation of the features of the problem that is being addressed. This is the key downside of LSTM.

4. Conclusion

Both the Novel Long Short-Term Memory and the Gaussian are components of the model that has been

proposed, with the Novel Long Short-Term Memory contributing the most to the overall values. The accuracy rate of Novel Long Short-Term Memory is 93.94% higher when compared to the accuracy rate of the Gaussian Algorithm, which has an accuracy rate of 74.88% in the research of share market stock price prediction. This is done in order to boost accuracy and precision and achieve Novel Long Short-Term Memory performance.

Abstract: The focus of the research is to apply a Novel Multi Keyword Scoring approach to shortlist resumes accurately in the process of getting jobs using Novel Multi Keyword Scoring Technique compared with Multinomial Bayes. To shortlist resumes accurately the keyword extraction technique has been used and the keywords are derived from a large resume dataset to get accuracy. The keywords are fetched to results using Novel Multi Keyword Scoring Technique using a sample size of 28 which gives the result of 80% G-power value. Using Novel Multi Keyword Scoring Technique the accuracy reached up to 75.04% while the K-Nearest neighbor got an accuracy of 73%. It shows that the difference is not significant between the Novel Multi Keyword Scoring Technique and KNN Algorithm with p=0.647 (p>0.05). In comparison to the K- Nearest neighbor algorithm's accuracy of 73%, the Novel Multi Keyword Scoring Technique has been able to achieve an accuracy of 75.04%. In addition, it has a subset of attributes with marginal distribution.

Keywords: Distance, feature vector, information, jobs, K-Nearest neighbor, natural language processing, novel multi keyword scoring technique

1. Introduction

The interaction between computers and human languages is the focus of the discipline of artificial intelligence and computer science known as natural language processing. NLP algorithms and models use methods from linguistics, computer science, and machine learning to evaluate and comprehend the structure and meaning of the language. By locating and extracting pertinent information from resumes and comparing it to the specifications of a jobs ad, natural language processing can be utilized to assist in automating the process of resume shortlisting. The use of keyword extraction in process of recruiting people for jobs is an Novel Multi Keyword Scoring Technique method that NLP can be applied to this situation. This entails locating the most important abilities and credentials given in a CV and contrasting them with those specified in the job description. A CV may be given a higher priority for inspection if it has a lot of keywords that are relevant to the jobs and is therefore thought to be a better fit [5, 19] which entails figuring out the overall sentiment or emotion portrayed in a text, is another method that NLP can be employed in the resume shortlisting process. This can be used to evaluate the tone and presentation of a resume and the compatibility of the applicant with the workplace culture. Information retrieval, data mining, and content analysis are a few examples of jobs that are the applications for NLP [12] in terms of accuracy and efficiency.

2. Materials and Methods

The research was developed in the Natural Language Processing lab at Saveetha School of Engineering, Saveetha Institute of Medical And Technical Sciences, which is equipped with finely configured equipment and NLP software that supports my work. Two groups, one for the proposed algorithm which is group 1 Novel Multi Keyword Scoring Technique), with a sample size of 28, and the other for the comparative algorithm which is group 2 K-Nearest Neighbor, also with a sample size of 28 were used for the investigation. With G-Power set to 80% and alpha, beta, and confidence level set to 0. 2, and 95%, respectively, the computation is carried out. The research uses the extended AI version for the interview screening process. The highlights come from the extensive resume dataset that was taken from Kaggle. Both the K-Nearest neighbor method and the Novel Multi Keyword Scoring Technique are tested on the collected data set. There are 963 rows in the dataset, and each row has two attributes: category, which represents the candidate's chosen area of interest, and resume, which represents their skill set. On this dataset, the methods K-Nearest neighbor and the Novel Multi Keyword Scoring Technique are used to train and assess the algorithms for extracting keywords that fit the job description. Since it offers strong processing resources like GPUs and TPUs, which can be utilized to carry out difficult computations and used to develop and validate machine learning methods, it is particularly suited for data science and artificial intelligence applications.

2.1. Novel multi keyword scoring technique

A Novel Multi Keyword Scoring Method, a keyword identification method that tries to match the identified phrases to the targets in order to take accurate objective selection into account, is applied to sample preparation group 1 as a proposed algorithm group 1. After determining the amount of terms that fit the goal, it presents that specific application as an appropriate option. Because the algorithm chooses the terms needed by the job description of the company to acquire permission for the accurate resume, this performs great for resume screening. The most effective method for removing informational value from word strings is by keyword selection. The best favored method is automation resume shortlisting because it would take a long time to complete the entire procedure manually. In order to calculate the percentage of

similar instances among the submitted job descriptions, Novel Multi Keyword Scoring Technique determines the entire number of terms that connect the training and testing sets of data. Table 98.1 demonstrates the Novel Multi Keyword Scoring Technique's pseudocode.

2.2. K-nearest neighbor algorithm

KNN could be used as a tool to help automate the process of choosing which resumes are the most pertinent to a certain jobs opportunity in the context of resume shortlisting. In the resume shortlisting process using KNN First, the resumes of past successful candidates for the job in question would be collected and labeled as "relevant" resumes. These resumes would serve as the training data for the KNN algorithm. The resumes of current job applicants would then be processed and transformed into a set of numerical features that capture information about the applicant's education, work experience, skills, and other relevant details. These feature vectors would be used as the input data for the KNN algorithm. The KNN algorithm would then compute the distance between each applicant's feature vector and the feature vectors of the relevant resumes in the training data. The K nearest neighbors to each applicant's feature vector would be identified based on this distance measure. The algorithm would then use the labels (i.e., "relevant" or "not relevant") of the K nearest neighbors to determine the label for each applicant's resume. For example, if the majority of the K nearest neighbors are labeled as "relevant," the algorithm would predict that the applicant's resume is also relevant. The resumes of the applicants who are predicted to be the most relevant could then be shortlisted for further review by a human recruiter.

2.3. Statistical analysis

IBM SPSS (Statistical Package for the Social Sciences) version 26 software, which offers capabilities for managing data and doing statistical analysis, is used for statistical analysis. SPSS is used to assess the precision of classifiers in the framework of automatic resume shortlisting utilizing the Novel Multi Keyword Scoring Technique and K-Nearest neighbor (KNN). Most commonly, statistical procedures like mean, f-value, standard deviation, standard error mean, significance value, and df are calculated using the SPSS application. Here, the length of the resume and the number of keywords that appear in the text serve as independent variables while the accuracy serves as the dependent variable [6].

3. Tables and Figures

Table 98.1. A procedure for the innovative multi keyword scoring method is shown in Table 98.1

Input: Raw-Text (Resume Dataset)
Output: Accuracy of similarity
Step 1: Convert the raw data by purging it of unnecessary characters.
Step 2: The second step is to break the dataset up into phrases and load it into CSV files. Tokenize the data and store each one separately in step three.
Step 3: Using the NLTK library, remove unwanted stop - word from the dataset.
Step 4: Compare the tokens with the specified stop words, and eliminate any words that match.
Step 5: Keep the terms that define distinct meaning in step five.
Step 6: Use stemming to obtain the various word roots.
Step 7: Compile a corpus of all the root terms and determine whether they accurately reflect the language.
Step 8: Complete the scoring procedure by tallying the amount of words that correspond to the pre-selected training data keywords, and assess metrics like precision, recall, and accuracy.
Step 9: Expand the training set to see if the accuracy is changing, and record the values of the accuracy.

Table 98.2. The Procedure for the K-Nearest Neighbor classifier is presented in Table 98.2. To execute the algorithm, it is essential to download all the necessary Python libraries

Input: Raw-Text (Converted Vector Values)
Output: Accuracy similarity
Step 1: Collect and label the resumes of past successful candidates for the job in question as "relevant" resumes. These resumes will serve as the training data for the KNN (K-Nearest Neighbor) algorithm.
Step 2: Preprocess and extract features from the resumes of current job applicants. These features could include information about the applicant's education, work experience, skills, and other relevant details.
Step 3: Define a distance measure that will be used to compare the feature vectors of the applicants' resumes to the feature vectors of the relevant resumes in the training data.
Step 4: Initialize the value of K, which determines the number of nearest neighbors that will be used to make a prediction.
Step 5: For each resume in the applicant pool: Step 5.1: Calculate the distance between the resume's feature vector and the feature vectors of the relevant resumes in the training data using the defined distance measure. Step 5.2: Identify the K nearest neighbors to the resume's feature vector based on the distance measure. Step 5.3: If the majority of the K nearest neighbors are labeled as "relevant," predict that the resume is also relevant. Step 5.4: If the majority of the K nearest neighbors are labeled as "not relevant," predict that the resume is not relevant.
Step 6: The resumes of the applicants who are predicted to be the most relevant can then be shortlisted for further review by a human recruiter.

4. Results

A Procedure for the Innovative Multi Keyword Scoring Method is shown in Table 98.1. The Procedure for the K-Nearest Neighbor classifier is presented in Table 98.2. The raw data table for evaluating the accuracy of both Novel Multi Keyword Scoring Technique and K-Nearest neighbor is shown in Table 98.3. The statistical calculations for independent samples that compare the Novel Multi Keyword Scoring Method with the K-Nearest Neighbor method are shown in Table 98.4. The Novel Multi Keyword Scoring method's mean accuracy is 75. The Novel Multi Keyword Scoring approach has a standard deviation of 17. A T-test was used to compare the standard mean errors of the Novel Multi Keyword Scoring Method with the K-Nearest Neighbor method using a distinct sample. Table 98.5 The Novel Multi Keyword Scoring Method and the KNN Algorithm are compared in this table using statistically independent samples, with a confidence interval of 43.7%. The Innovative Multi Keyword Scoring Method has a little greater mean accuracy than the K-Nearest Neighbor Classifier and a slightly bigger standard deviation. K-Nearest Neighbor Detection accuracy on the Y axis is mean +/- 1 SD.

5. Discussion

Automatic resume shortlisting was already done in the past using machine learning algorithms, but NLP is an Novel Multi Keyword Scoring Technique approach and it has been stated that if they are applied in the future utilizing NLP, the accuracy value will be higher [17]. Because the phrase rank is sustained all through the parsing process, the Novel Multi Keyword Scoring technique produces better results in the article quoted Speech recognition uses NLP, although it can be challenging to extract text from speech. In the current study, keywords are extracted from text data to make the dataset easier to load using the Novel Multi Keyword Scoring Technique. Both K closest neighbor and a Novel Multi Keyword Scoring Technique can be utilized in the context of automatic resume shortlisting to help determine which resumes are the most pertinent for a particular job opportunity. KNN is a machine learning algorithm that requires a set of

Table 98.4. Statistical computations for independent samples that compare the K-nearest neighbor with the Novel multi keyword scoring technique. The mean accuracy of the Novel multi keyword scoring method is 75.04%, whereas the K-nearest neighbor is 73.00%

	Algorithm	N	Mean	Std. Deviation	Std. Error Mean
Accuracy	Novel multi keyword scoring	28	75.04	17.221	3.254
	k-Nearest neighbor	28	73.00	15.825	2.991

labeled training data to learn from, it uses a distance measure to compare the input data to a set of labeled examples (e.g., relevant and non-relevant resumes) and makes a prediction based on the labels of the nearest neighbors. A Novel Multi Keyword Scoring Technique on the other hand, is a rule-based approach that simply counts the number of specified keywords present in a document and assigns a score based on this count. Another difference is the types of tasks each approach is best suited for. The factors affecting the study when comparing KNN with Novel Multi Keyword Scoring Technique are quality of training data, choice of distance measure, value of k, keywords, evaluation metrics. Carefully selecting keywords that are representative of the content of relevant resumes and

avoiding keywords that are too specific or too general could increase the performance of the Novel Multi Keyword Scoring Technique. Overall, there is future scope for the Novel Multi Keyword Scoring Technique in the context of automatic resume shortlisting, and incorporating these and other approaches could lead to more accurate and efficient methods for identifying relevant resumes.

6. Conclusion

For both the Novel Multi Keyword Scoring Technique and KNN, the huge resume dataset is employed as a training sample in the automation of the resume shortlisting process. When compared to KNN, the Novel Multi Keyword Scoring Technique appears to extract keywords more effectively. Compared to KNN (K-Nearest Neighbor) accuracy numbers of 73%, the Novel Multi Keyword Scoring Technique offers a 75.04% accuracy rate. The accuracy of the Novel Multi Keyword Scoring Technique enhanced.

99 An effective approach for prediction of sensors uncertainty in agriculture using maxima algorithm over linear regression algorithm

Jyothi Ram[a] and N. Deepa

Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The aim of the research is to specify the water wastage management system in agriculture by comparing Novel maxima algorithms with Linear regression algorithms. The precision value of crops is given using the dataset. Materials and Methods: In order to achieve the G power of 80%, the accuracy is achieved utilising the Novel Maxima Water Waste Management Algorithm and the Random Forest Algorithm Solution with N=24 and N=48 Samples. Results: The proposed algorithm has the mean precision of (77.96%) and it is greater than the comparison algorithm (73.79%) in the water measurement. It shows that there is no statistical significance difference between the Novel Maxima algorithm and Linear Regression algorithm with The study's results were considered no statistically significant as the calculated $p=0.389$ (Independent sample T-Test $p>0.05$) was below the commonly accepted threshold of 0.05, indicating that the observed findings were unlikely to be due to chance alone. Conclusion: Novel maxima algorithm has the greater mean precision (77.96%) than the linear regression algorithm (73.96%).

1. Introduction

Water management is used to measure the water measurement for the future generation by using the new techniques. To select a model, the data scientist will typically choose a model that is appropriate for the task at hand, based on the type and structure of the data and the goals of the project. It is an important step in the machine learning process because the quality and structure of the data can significantly impact the performance of the trained model. The main applications of Machine learning can be used to develop algorithms that can analyse medical data and make predictions or recommendations for patient care, such as for diagnosis or treatment plans. In agriculture the water measurements are used to store the quantity of water measurement these scholars found in the IEEE explore, Springer and the Science director. They

are the many citations they cite, the many variations through the water management level and changes to many areas to itself and based on the water level Water measurement and climate change using sensors in agriculture can help farmers optimise the use of water resources and crop yield. Sensors can also be used to monitor temperature and humidity, which can provide information about the weather conditions and the evapotranspiration rate of the crops. This can help farmers optimise irrigation schedules and apply the right amount of water to the crops at the right time. In addition to optimising irrigation, sensors can also be used to monitor other factors that affect crop growth, such as nutrient levels in the soil and pests. The use of sensors in agriculture can help farmers make more informed decisions about water management and crop yield, leading to more sustainable and efficient use of water resources.

2. Materials and Methods

Data analytic lab is available in the Saveetha School of Engineering where the research was conducted in the Saveetha Institute of Medical And Sciences which has a best quality layout system for giving studies and getting results. The calculation is defended with a G power of 80%, alpha and beta values of 0. The main data that is present in the dataset is about the process of agriculture and planting certain trees and different times of climate. That shows about the various water levels used for the crops in farming. The proposed algorithm is used to demonstrate the correct usage and evaluate the water quality in a water management system. To compare the performance of the proposed algorithm with another algorithm, a dataset is used as input to both algorithms and their output is compared. The comparison is done by executing both algorithms and using the results to make a comparison. Google Collab is a cloud-based tool that allows users to efficiently work on projects and code through the cloud. Code can be saved in Google Drive before it is executed, making it easy to access and work on from any device. This allows users to access and work on their projects and code from any device without the need for additional setup or configuration packages or tools are used to process and interpret the input data provided influence food production.

2.1. Novel maxima algorithm

The Novel maxima algorithm can be defined as what the sample preparation group 1 used to arrive at the one solution. Novel Maxima algorithm is a computational method that aims to identify the maximum value or highest peak in a dataset. The version of the algorithm may involve various modifications or enhancements to the original algorithm to make it more efficient or accurate. These modifications could include changes to the way the algorithm processes data or the implementation of additional techniques its performance. The purpose of the Novel maxima algorithm is to identify the highest value or peak in a dataset accurately and efficiently. This is achieved through various modifications or enhancements to the original algorithm to its performance and accuracy. Algorithms can be used to help identify and change in climate resolve problems by identifying both the highest and lowest potential outcomes. This algorithm is designed to assist in solving problems related to agriculture and climate by identifying the most efficient path for addressing complications in various processes. The real-life application of this algorithm is focused on problem-solving and finding the most accurate solution to a given problem.

The procedure of the Novel maxima algorithm is represented in Table 99.1.

2.2. Linear regression algorithm

Linear regression is an easy and most used machine learning algorithm. To find the predictive analysis, linear regression is used. This algorithm shows the relationship between dependent and independent variables which is linear. As the relationship is linear we can find out how the dependent values are changing based on the values of the independent values. The relationship between the dependent and independent variables is linear which is also called a regression line. It is also defined as the statistical model which analyses the linear relationship. Positive linear regression, if the regression line is increasing then the relationship is positive linear relationship. Negative linear regression, if the regression line is decreasing then the relationship is negative linear relationship. Linear regression is a statistical method that is used to model the linear relationship between a dependent variable and one or more independent variables. The procedure of the Linear regression algorithm is represented in Table 99.2.

2.3. Statistical analysis

Statistical software such as SPSS version 26.0 can be used to calculate various values, including the standard deviation, mean, standard error mean, mean difference, and f values. In this analysis, the dependent variables might include land usage, water stored, and land usage, while the independent variables might include the quantity of water used and precision as an outcome.

3. Tables and Figures

Table 99.1. Procedure for the Novel maxima algorithm which is the proposed algorithm. After the subsets of the problem have been reduced to their minimum size, the Novel maxima algorithm will identify the unique solution for each subset of the problem

Input: Water usage dataset
Output: Precision rate of water usage
Step 1: Pick a process from the problem's root node. Step 2: Decide which child node has the least value. Step 3: Continue selecting nodes until all of them have been selected. Step 4: The optimal path is obtained. Step 5: Using the local minima, the global results are obtained.

Source: Author.

4. Results

Based on the analysis the Novel maxima algorithm has high precision when compared to Linear Regression algorithm. Table 99.1 shows the procedure of the Novel maxima algorithm. The first step in the algorithm is to start at the starting point of the problem and minimise it to find the exact solution. Table 99.2 shows the procedure of the Linear Regression algorithm. This algorithm finds the data on the dependent variable and the independent variables that are of interest and it has the relationship between the variables. Table 99.3 shows that both algorithms are present and explain the values of the Novel maxima algorithm and the Linear Regression algorithm. Table 99.4 shows the various values of the Novel maxima algorithm are N, standard deviation, standard error deviation, mean and for the Linear Regression algorithm values are N, mean, standard deviation , standard error deviation. Table 99.5 shows different values of the t values samples they are Standard error difference, mean difference, these values for the Novel maxima algorithm and the other values are mean difference, standard error difference, these are for Linear Regression algorithm.

Table 99.2. Linear Regression algorithm procedure. This algorithm helps to find the solution in the fast method and in the less cost purpose. By the use of the dataset it finds the solution with the shortest path

Input: Water usage dataset
Output: Precision rate of the water usage
Step 1: The first step is to collect data on the dependent variable and the independent variables of interest.
Step 2: Before conducting the analysis, it is important to ensure that the data is clean and accurate.
Step 3: It is used to plot the point, a sense of the relationship between the variables.
Step4: Based on the patterns observed in the data and select the value.
Step 5: Once a model has been chosen, the next step is to estimate the model parameters

5. Discussion

The main problem at present is the usage of the water management in a certain range of amounts. Where the high water wastage in larger quantities. There are several sources of uncertainty in agriculture that can impact the accuracy and reliability of sensors used for water management systems. These changes can impact the accuracy and reliability of the precision rate 87% sensor readings. The accuracy of the precision rate 85% sensor readings can be affected by the location of the sensor. There the precision rate 86% are several factors that can affect the accuracy and reliability of sensors used in agriculture for water management

systems. There the precision rate 82% are several sources of uncertainty in agriculture that can affect the accuracy and reliability of sensors used in water management systems, leading to the wasteful use of large amounts of water. Climatic conditions in areas with high levels of evaporation or precipitation, more water may be required to maintain crops, increasing the risk of water wastage and affecting climate. The limitations of the water management system in agriculture are cost. Water management systems can be expensive to implement and maintain, particularly for small farmers who may not have the resources to invest in such systems. The main future work of water management are more efficient irrigation systems that use less water and have a lower risk of water wastage.

6. Conclusion

By the comparison of the two different algorithms of the Novel maxima algorithm and the Linear Regression algorithm, having the dataset of each dataset contains the various values for the implementation. When the two different algorithms are compared the rate of the precision is higher for the Novel maxima algorithm (77.96%) then compared to the Linear Regression algorithm (73.79%).

Abstract: The analysis principal aim is to compare the accuracy of understandability between Term Frequency Inverse Document Frequency (TF-IDF) and Novel Rapid Automatic Keyword Extraction (RAKE) in the NLP (Natural Language Processing) relying on the corpus of Donald Trumph speeches for making squarified maps from huge data. To retrieve keywords from a single text or a bunch of documents, use the accuracy calculations. Utilizing the Novel RAKE and TF-IDF algorithms with sample sizes of 28 and 28, respectively, this key phrase gathering is taken out using NLP (Natural Language Processing), producing a G-power result of 80%. The Novel Rapid Automatic Keyword Extraction (RAKE) method generates an accuracy rate of 73.50%, which is better than the accuracy rate of 66.39% generated by the Term Frequency Inverse Document Frequency (TF-IDF) algorithm. It shows that there is no statistical significance difference between the Novel RAKE algorithm and the TF-IDF algorithm with p=0.076 (p>0.05). The Novel RAKE approach is successful in achieving a prediction accuracy of 73.50%, comparing the TF-IDF (Term Frequency Inverse Document Frequency) algorithm's prediction accuracy rate of 66.39% and a selection of characteristics or parameters in marginal distribution.

Keywords: Donald Trumph speeches, key phrases, natural language processing, novel rapid automatic keyword extraction, term frequency inverse document frequency, produce

1. Introduction

There are so many approaches for processing texts [19] in natural language utilizing keyword grabbing. BERT, lemmatize the material, summarize the content, and POST (Parts-Of-Speech-Tagger) are a few of them. All of these approaches [9] are useful for analyzing the text. Some techniques for the collecting of key phrases from all documents in NLP like Novel RAKE, YAKE, BOW, etc. As already known, the data exists in two different forms. There is structured content and unstructured content. Structured content can be easily analyzed through graphs [2,4,8] and systematic measures. But processing and examining unstructured text requires some techniques [13,17,22]. Unstructured content can be dealt with easily with NLP. The unstructured content exists on the web, in PDFs, log files, etc. The algorithm can produce so many journals and articles after examining and filtering the key phrases from the content. Grammar checking, chatbots, human voice interpretation, and voice virtual assistants are instances of NLP application [21] domains.

[a]riteshsmartgenresearch@gmail.com

In the study area for most-valued phrases collected from all documents, several research publications and articles in IEEE and Science Direct exist. In the medical field, the potential of NLP approaches is growing rapidly in the present day. Primarily, NLP collects data and allows for the sharing of electronically protected medical records. The examples for structures are POS, defining the meanings of every word to show off grammar in branches. For the purpose of mapping vast chunks of data to important key phrases, the Novel RAKE algorithm can use NLP. Here "natural language" refers to the language used by human beings to talk to each other, which is mainly speaking and texting. Many different algorithms exist in NLP for various purposes like language change, examining the type of content, and so on. The existing technique Novel RAKE is preferred since as a limitation, the TF-IDF takes a lengthy time to obtain crucial words from larger text files. The analysis's principal aim is to differentiate the accuracy between Term Frequency Inverse Document Frequency and Novel Rapid Automatic Keyword Extraction in the NLP relying on the corpus of Donald Trumph speeches. As a response, a chart that illustrates an understanding of the text and is focused on the phrases with the maximum score weights amongst a massive amount of text is produced.

2. Materials and Methods

For the two groups that were utilized to assess the algorithmic accuracy rate, the sample size is 28. The computation is accomplished using the G-power value of 80% together with alpha, beta, and confidence-interval values of 0. Donald Trumph speeches is the dataset helpful to contrast Novel RAKE with TF-IDF. The Donald Trumph speeches dataset comprises 1071 sentences and 9472 words. The Donald Trumph speeches dataset was pulled out from Kaggle. The dataset including the words Donald Trumph used during his well-known talks contains a substantial amount of text. The document that utilizes for training and testing is 51764 words long. One of the greatest datasets for understanding insight into the Novel RAKE and TF-IDF algorithms for grabbing significant words from the dataset is the Donald Trumph speeches dataset. The collab is an environment free of Jupyter notebooks. Actually, installing and configuring is not necessary for the collab.

2.1. Novel rapid automatic keyword extraction

From the content supplied by the source, Novel RAKE pulls the most-ranked key phrases. The Novel Rapid

Automatic Keyword Extraction identifies and evaluates how the words occur with other words in the text through utilizing co-occurrence graphs. Based on the builded matrix, the Novel RAKE can give scores for each key phrase. Novel RAKE is an effective system for key phrase retrieval all key phrases include many words. The score for a unique key phrase is calculated from the plus of rank scores of each word in the key phrase. Novel RAKE is very beneficial to handle the checking of spelling and errors in grammar. Novel RAKE separates the content into sentences and then reduces those sentences by eliminating stop words. Stop words are the ones that define nothing. These stop words are a collection of words that vary in different languages. Table 100.1 denotes the procedure of Novel RAKE technique.

2.2. Term frequency inverse document frequency

As a sample preparation group 2, the TF-IDF is defined as the term "Term Frequency Inverse Document Frequency". The TF-IDF is utilized for gathering key phrases from numerous document types. While key phrases, the TF-IDF assesses the rareness of collecting key phrases, as well as word's frequency in a bunch of files. The TF-IDF algorithm is utilized to provide the appropriate definitions for each word and then evaluating key phrases based on their syntax. The TF-IDF is very efficient in solving the challenges of the BOW algorithm, which is easy for content classification. The TF-IDF can give scores for each and every key phrase, depending on the word frequency in each key phrase. The scores are generated by IDF. Then the scores and their key phrases are arranged in descending order. The key phrases that are at the top can be grabbed. Table 100.2 denotes the procedure of TF-IDF technique.

2.3. Statistical analysis

IBM SPSS is a practical instrument for doing research studies and is a solid option for evaluating statistics information from a wide variety of industrial domains[24]. There are 2 viewpoints in IBM SPSS: (1) variable view interpretation of the data, (2) data view interpretation of data. From the information reported in the data and variable view, SPSS creates a wide variety of graphs. The most used computations in SPSS are mean, F-value, standard error of means, significant level, and df. The volume of the textual big file, the quantity of words in it, and the accuracy of the estimated output are the dependent variables. Count of words pulled from the given dataset is the independent variable utilized in the system.

3. Tables and Figures

Table 100.1. The Novel RAKE algorithm's procedure is displayed in the table below. The model may then be trained using the retrieved dataset after installing all essential libraries. Both testing and training models are utilised in different purposes to determine the accuracy value

Input: Raw text (Donald Trumph speeches dataset)

Output: Accuracy rate of similarity

Step 1: Capture potential keywords by eliminating stop words.
Step 2: Develop the co-occurrence matrix for every key phrase.
Step 3: Analyze each candidate keyword's level of score.
Step 4: Compile the scores for every word in the key phrase, then sum them.
Step 4: Adjoin the key phrases.
Step 6: Measure how many key phrases have been discovered to match the manually defined key phrases.
Step 7: Assess the performance metrics, comprising recall, accuracy, miss rate, F-measure, and error rate.
Step 8: Develop a matrix for the Novel Rapid Automatic Keyword Extraction (RAKE) key phrases of various lengths that were both automatically determined and manually allocated.
Step 9: Chart the time duration spent using the Novel RAKE technique to identify key phrases for keywords of various lengths.
Step 10: Develop a squared chart with the top - ranked key phrases that Novel RAKE has gathered.

Table 100.2. The TF-IDF (Term Frequency Inverse Document Frequency) algorithm's procedure is displayed in the table below. The model may then be trained using the retrieved dataset after installing all essential libraries. Both testing and training models are utilised in different purposes to determine the accuracy value

Input: Raw text (Donald Trumph Speeches dataset)

Output: Accuracy rate of similarity

Step 1: Capture all of the data from the source text and tokenize the content into individual unique sentences.
Step 2: Once more, break the phrases up into words using tokenization.
Step 3: Stop words and get each word's TF (Term Frequency).
Step 4: Examine and compute each word's IDF score.
Step 5: Evaluates each word's TF*IDF score.
Step 6: Utilizing the TF*IDF scores, keep track of the extremely highly-scored terms.
Step 7: Collect all of the sentences that consist of higher important phrases.
Step 8: Create a conceptual model using the texts that were gathered and evaluate accuracy.

4. Results

Table 100.3 represents the Raw data table for assessing the precision of both the Novel RAKE (Rapid Keyword Automatic Extraction) and the TF-IDF algorithms. Table 100.4 denotes calculating statistical results for independent samples to compare Novel RAKE and TF-IDF algorithms. The Novel RAKE's mean accuracy is 73. The standard deviation value for Novel RAKE is 15. Table 100.5 refers to the calculating statistical results for independent samples to compare Novel RAKE and TF-IDF algorithms. 076, it is evident that there is no statistically significant difference between the Novel RAKE algorithm and the TF-IDF method. The Novel RAKE Algorithm has a higher level of keyword relevance than the TF-IDF Algorithm. X-axis: Total number of documents where Novel RAKE and TF-IDF identified matches for the given key phrases. The Novel RAKE Algorithm has a higher mean accuracy than the TF-IDF

Table 100.4. Calculating statistical results for independent samples to compare Novel RAKE and TF-IDF algorithms. The Novel RAKE's mean accuracy is 73.50, while TF-IDF is 66.39

	Algorithm	N	Mean	Std. Deviation	Std. Error mean
Accuracy	Novel RAKE	28	73.50	15.108	2.855
	TF-IDF	28	66.39	15.302	2.703

Algorithm and a slightly higher standard deviation than the TF-IDF Algorithm. X-axis: Novel RAKE vs TF-IDF Algorithm Y-axis: Mean accuracy of detection +/- 1 SD.

5. Discussion

The Novel RAKE should find and eliminate the words that are not useful to give any meaning to describe the text, that are defined as stop words. Then the Novel RAKE should identify the words that are co-occurring, and the Novel RAKE has to build a matrix based on co-occurring phrases. Then the Novel RAKE can assign the scores for each key phrase. To extract the score for every key phrase, the Novel RAKE has to add the scores of all
Figure 100.2. A bar chart for comparing the value of accuracy. The Novel RAKE Algorithm has a higher mean accuracy than the TF-IDF Algorithm and a slightly higher standard deviation than the TF-IDF Algorithm. X-axis: Novel RAKE vs TF-IDF Algorithm Y-axis: Mean accuracy of detection +/-1 SD.

Source: Author.

words that exist in that key phrase for accuracy of 72%. Evaluate the frequency for a unique word, and the TF-IDF considers the weight for that key phrase. The Novel RAKE uses many functions in the Novel Rapid Automatic Keyword Extraction algorithm to gather the main candidate key phrases that describe the document briefly. The Novel RAKE also supports a bunch of documents; the Novel RAKE can be applied to one unique document. The Novel RAKE is capable of comprehending both the syntax and the context of every word. Then the Novel RAKE can analyze the text and perform the processing. The Novel RAKE is a great challenge to overcome.

6. Conclusion

The rate of accuracy produced in Novel Rapid Automatic Keyword Extraction of 73.50% is more than the

rate of accuracy of Term Frequency Inverse Document Frequency is 66.39%. For getting perfect and accurate outcomes, the Donald Trump speeches dataset having a high quantity of textual content is used. The Novel RAKE technique has an adequate rate of efficiency and performance level when differentiated from TF-IDF. So, the Novel RAKE approach produces better outcomes for all key phrases gathered from the one unique document.

101 An effective approach to accurately recast giant text using rapid automatic keyword extraction algorithm in comparison with collaborative filtering algorithm

Gurusai Muppala[1,a] and Devi T.[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Research Guide, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The main goal is to examine the accuracy value of understandability in contrast with the methods Novel Rapid Automatic Keyword Extraction (RAKE) and CF (Collaborative Filtering) in NLP (Natural Language Processing) utilizing a corpus of Donald Trumph Speeches for getting squarified charts from large data. Materials and Methods: Accuracy rate calculation is performed to figure out which keywords should be extracted from which documents, whether one or many. With a sample size of 28 for the Novel RAKE strategy and 28 for the CF strategy, this key phrase grabbing is carried out using NLP (Natural Language Processing), delivering a G-power rating of 80%. Results: When retrieving key phrases from a text document, the CF (Collaborative Filtering) procedure of accuracy of 62.75% works less accurately than the Novel Rapid-Automatic-Keyword-Extraction (RAKE), with a rate of accuracy of 72.79%. It demonstrates that the Novel RAKE algorithm and the CF method vary statistically significant, with $p = 0.021$ $(p < 0.05)$. Conclusion: When opposed to the CF method's accuracy percentage of 62.75% and a range of features or factors in marginal distribution, the Novel RAKE strategy is efficient in achieving an accuracy rate of 72.79%.

Keywords: Collaborative filtering, Donald Trumph speeches, key phrases, natural language processing, novel rapid automatic keyword extraction, produce, stop words

1. Introduction

The approach to processing and analyzing the text through some defined theories and technologies is said to be "Natural Language Processing". It is a method of capturing human-like language processing from naturally occurring text processing and analysis. The aim of natural-language processing is to achieve a human-like processing of languages. But NLP is used to know all the textual content and for the realization of natural language for unstructured data. NLP technique is helpful to examine the expressions and their feelings like sadness, happiness, etc., which is called analysis of human sentiments. There are so many futuristic applications for NLP, like interacting closely with humans through multimedia devices. To recognise the voices of humans, grab the content from it through the processing of its natural language

[15]. It has made major contributions to computer science in the specific area of machine learning and also linguistic analysis. In NLP, the software takes input from the user, identifies and learns the structure of the text, studies the definition of human language, and then provides the output to the user. The main aim is to examine the accuracy of understandability between the methods Novel Rapid Automatic Keyword Extraction and CF in NLP utilizing a corpus of Donald Trumph Speeches. The final outcome is the development of a chart that is relying on the Novel RAKE strategy's ability to locate essential terms from a text.

2. Materials and Methods

Saveetha Institute of Medical and Technical Sciences, Natural-Language-Processing Laboratory of the Saveetha School of Engineering, supplies well-equipped systems for monitoring training data for the study of research. The sample size for the two groups utilized to obtain the algorithmic accuracy rate is 28. 95 and 95%, respectively, the analysis is finished using the G-power value of 80% by employing clinical software. The entire speech files in the Donald Trumph Speeches dataset, which is acquired from Kaggle, were to create distinctive key phrases. Both the Novel RAKE and CF methods are used to evaluate this extracted dataset. For training and evaluation, this dataset of Donald Trump speeches is supplied to the Novel RAKE and CF techniques in order to recognize crucial phrases. The installation of a variety of machine-learning libraries available via Google Collab. The collab offers free cloud-based services that use a free GPU. Users may mine datasets from several other sites like Kaggle utilizing the collab. For the optimal outcomes from algorithm computation, use collab version 3.

2.1. *Novel rapid automatic keyword extraction (RAKE)*

As a sample proposed algorithm group 1, Novel Rapid Automatic Keyword Extraction (RAKE) is a system for retrieving content. For obtaining key words from the text, use the Novel RAKE approach, which is independent of domains and languages. This algorithm has a list of stop words and delimiters. Using that list, some words can be stopped or dropped from the sentences in the text. Then it can get all the candidate keyphrases. It can generate graphs for co-occurred phrases based

on candidate key-phrases. Then evaluate the degree and frequency for each phrase. By finding ratios for both degree and frequency, the Novel RAKE can build a matrix for each phrase based on score and weight. There are so many application domains for Novel RAKE, like summarizing legal texts and classifying patent keywords. Table 101.1 denotes the procedure for the Novel RAKE algorithm.

2.2. *CF (Collaborative Filtering)*

As a sample comparison algorithm group 2, CF (Collaborative Filtering) is helpful for knowing user interests based on the interests of other users who are related. In CF algorithms, there are two types of approaches: 1) Memory-based method 2) A model-based method it is mainly used in applications like review systems, where users can be filtered based on the reviews they produce. Observe, users can produce ratings in the past, and based on that, this method provides fresh content that will definitely be liked by users. So the content that is provided to users depends on the method of likeness used in the past. The ratings of users maintained in the database are helpful to filter. CF (Collaborative Filtering) strategy has many applications in e-commerce. So the users who produce the same ratings for the same contents are considered related, which means they have equal preferences. Table 101.2 denotes the procedure for the CF algorithm.

2.3. *Statistical analysis*

Data generation, information gathering, and statistical analysis [3,11] are the principal functions of the SPSS, which is also employed for file reorganization. Two different modes of viewing are available in IBM SPSS: 1) Data analysis utilizing the variable view, and 2) Data analysis utilizing the data view. With the information in the data and variable views, SPSS implements a wide variety of graphs. A vital feature of SPSS's data management strategy is reorganization. The storage of metadata concurrently with file data. In SPSS, the metrics mean, F-value, standard error of means, significant level, and df constitute the most frequently used metrics. For organizing research initiatives, IBM SPSS is a great resource. It also serves as a [3,11] solid option for interpreting statistical data from plenty of industrial domains. The dependent variables are the size of the document, the number of words in the large text document, and the precision of the anticipated output.

3. Tables and Figures

Table 101.1. The procedure for the Novel RAKE algorithm is shown in the table that is below. Prior to training the model with the retrieved dataset, all required libraries may be installed. The value of accuracy is calculated in a variety of ways using both testing and training models

Input: Raw text (Donald Trumph Speeches dataset)
Output: Accuracy of similarity
Step 1: Gather the keywords by removing stop words from the sentences. Step 2: Next, grab all the phrases that appear between each pair of stop words. Step 3: Next, Novel RAKE creates a graph or matrix of all the co-occurring words. Step 4: Assign scores for each word. Step 5: Calculate word degree and frequency, then find the ratio between them; after that, build the score-weight matrix for all phrases. Step 6: Get scores for each phrase by plus scores for each word in the phrase. Step 7: Based on the scores, obtain the top-ranked keywords. Step 8: Pull off the sentences that are having more key phrases. Step 9: Compute the accuracy value and build a concept chart from the grabbed sentences.

Table 101.2. The procedure for the CF algorithm is shown in the table that is below. Prior to training the model with the retrieved dataset, all required libraries may be installed. The value of accuracy is calculated in a variety of ways using both testing and training models

Input: Raw text (Donald Trumph Speeches dataset)
Output: Accuracy of similarity
Step 1: Separation of sentences from the text Step 2: Then, using stop-words from NLTK, remove them from all the sentences. Step 3: Next, collect all the phrases that fall between two stop-words. Step 4: Next, look for similarities between phrases based on the number of times they appear. Step 5: Then multiply the frequencies of phrases by a multiplication factor, and then we can find the missing rate of phrases with fewer frequencies. Step 6: Next, find the phrases that are similar and give them a higher score. Step 7: Next, select the top-scoring phrases. Step 8: The sentences that are having more key phrases can be pulled off. Step 9: Compute the rate of accuracy.

Figure 101.1. For the comparison of manually supplied key phrases with keyword extractions, use a line plot. Novel RAKE Algorithm's keyword similarity is higher than CF Algorithm. Number of keywords picked up by Novel RAKE and CF, along the X-axis. Y-axis: The quantity of personally chosen keywords.

Source: Author.

Table 101.5 denotes the statistical analysis of independent samples for the Novel RAKE and CF algorithms comparison. It demonstrates that the Novel RAKE algorithm and the CF method vary statistically significantly, with p=0. Number of keywords picked up by Novel RAKE and CF, along the X-axis. The Novel RAKE Algorithm's standard deviation is marginally higher than the CF Algorithms, while its mean accuracy is higher than the latter.

Figure 101.2. For comparison, use a bar graph. The Novel RAKE Algorithm's standard deviation is marginally higher than the CF Algorithm, while its mean accuracy is higher than the latter. X-axis: Novel RAKE vs CF Algorithm, Y-axis: Mean accuracy detection +/- 1 SD.

Source: Author.

5. Discussion

75%, higher than the Novel RAKE method's accuracy level of 72.79% while the Novel RAKE strategy's rate of significance is 0. Novel RAKE is not statistically significant different since the Novel RAKE strategy's significance score is less than 0.05. In Novel Rapid Automatic Keyword Extraction, The Novel RAKE can identify and get keywords from the text. The Novel RAKE algorithm produces a higher precision, F-score,

and recall score from the evaluation of all the extracted keywords from the text of accuracy 69%. The rapid keyword extraction process is quick and efficient, and it is simple to implement and has accuracy of 67%. The CF algorithm is also used in most of the domains [2], like news-recommended systems that are having the accuracy of 60%. As the Novel RAKE knows, for cinema recommended systems, the Novel RAKE can mostly use the NN approach. In the Novel RAKE algorithm, if Novel RAKE does not have the exact list of stop words, then it will not produce the correct keywords and key phrases. This Novel RAKE algorithm grabs the exact structure of meaningful phrases. As compared to other approaches for key-phrase extraction, Novel RAKE is the best one, representing high accuracy values.

6. Conclusion

The Novel RAKE approach has a respectable rate of efficacy and performance level in comparison to CF. The dataset of Donald Trumph Speeches, which contains a large amount of text, is used to provide results that are perfect, accurate, and trustworthy. The Novel RAKE strategy delivers better ratings for the key phrases pulled from the content. The accuracy level of Novel RAKE (72.79%) is higher than that of CF (62.75%).

102 Comparison of accuracy for novel optical character recognition technique over K-nearest neighbor algorithm to extract text from image and video

Sandhya Muppala[a] and Devi T.

Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The main aim of this research is the comparison of Novel Optical Character Recognition (NOCR) Technique with K-Nearest Neighbor (K-NN) algorithm to extract text from image and video for improving accuracy. To extract keywords from a single document or a collection of documents, utilize the accuracy calculation. This Extraction of text is done by Natural-Language-Processing using the Novel OCR algorithm with a sample size of 22 and the K-Nearest Neighbor algorithm with a sample size of 44 that gives the result of an 81.95% G-power value. The accuracy produced by the Novel Optical Character Recognition algorithm is 81.95%, which is higher than K-Nearest Neighbor algorithm's accuracy of 78.32%. It shows that there is no statistical significance difference between the Novel OCR algorithm and K-NN algorithm with $p=0.254$ ($p>0.05$). Compared to the accuracy of K-NN, which is 78.32%, the Novel Optical Character Recognition method has a high accuracy rating of 81.95%. Discrete Cosine Transform, Fast Fourier Transform, K-Nearest Neighbor, Natural Language Processing, Novel Optical Character Recognition, Simple Logistic, Technology Transfer.

Keywords: Text from image, text from video, optical character, tecnique of K-nearest

1. Introduction

It involves using machine learning algorithms and other techniques to process and analyze large amounts of natural language data, Discrete Cosine Transform, such as text or speech. For example, the same word can have multiple meanings depending on the context in which it is used, and the meaning of a sentence can change based on the words that come before or after it. As a result, NLP systems must be able to understand the context in which language is used and make intelligent decisions based on that context. Information extraction and Simple Logistic in NLP techniques can be used to extract structured information from unstructured text, such as extracting names, dates, and locations from a news article. Named entity recognition in NLP can be used to identify and classify named entities in text [2]. In the field of study for key phrase extraction from text documents, there are several research publications and articles in IEEE and Science Direct. Part-of-speech tagging,

NLP can be used to identify the part of speech of each word in a sentence, such as nouns, verbs, and adjectives. Summarization of NLP can be used to generate a summary of a long document or multiple documents by extracting the most important information NLP can be used to translate text, Technology transfer from one language to another, allowing for cross-language communication and information sharing. The text extraction can be used for searching important information from the huge amount of video data set. The main goal of this research is the comparison of Optical Character Recognition Technique with K-Nearest Neighbor algorithm to extract text from image and video for improving accuracy.

2. Materials and Methods

The research was carried out in the Natural-language-processing lab at the Saveetha School of Engineering and Saveetha Institute of Medical and Technical

Sciences, which has highly configured machines or systems for better and more accurate outcomes from training data. 22 people make up the sample size for the two groups. G-power is set to 80% for the computation, and alpha, beta, and confidence intervals are set to 0. The new key phrases are compiled from the voice files in the entire BBC news dataset that was taken from Kaggle. The Novel OCR and K-Nearest Neighbor methods are used to test this extracted dataset. The total number of images and videos in this collection is 30. This dataset of BBC news is supplied to the Novel OCR and K-Nearest Neighbor algorithms for training and evaluating in order to detect significant phrases and Technology transfer and Fast Fourier Transform. This study's major objective is to better accurately extract information from photos and videos. It makes for a great platform for machine learning and data science jobs since it gives users access to a variety of processing resources, such as GPUs and TPUs. Access to a variety of hardware resources, such as CPUs, GPUs, and TPUs, is made available through Collab.

2.1. Novel optical character recognition algorithm

Novel Optical Character Recognition as a sample preparation proposed algorithm group 1. The application of Novel OCR is scanning of a document for digitizing text. Data entry to business documents, automatic number plate recognition, key information extraction, extracting business card information into a contact list. It is a type of technology that allows us to extract the information and Technology transfer from the document and turn it into searchable and editable data. Whether the documents are coming in as physical pieces of paper that need to be scanned in or something a non-searchable PDF, Discrete Cosine Transform, Novel OCR is going to allow you to digitize that information. Once we extract the information of a document, we are able to pass it along to other systems, like an ERP or a content management platform for process management. The common example of a Novel OCR is invoice processing, Technology transfer, Human resources and legal document searchability, transcript processing and sales processing. The text can be easily translated into multiple languages, making it easily interpretable to anyone. Novel Optical Character Recognition is not limited to the detection of text from document images only. Table 102.1 denotes the pseudocode of the optical character recognition algorithm.

2.2. K-NN (K-Nearest Neighbor) Algorithm

A non-parametric supervised machine learning approach for classification and regression is known as the K-Nearest Neighbour algorithm. The item is classified for text classification using the K-nearest neighbors' votes. The class of the item is determined by the class with the greatest number of neighbor votes. Euclidean distance and other distance metrics are used to calculate the K-NN. The generalization of the training dataset is postponed until the evaluation is complete in the K-NN type of instance-based learning and lazy learning. It is a data classification method for estimating the likelihood that a data point will become a member of one group or another based on what group the data points nearest to it belongs to. The K-nearest neighbor algorithm is used to solve the classification and regression problems. The testing process is slower and more time- and memory-intensive, extremely sensitive to anomalies. The quantity of data must grow exponentially as the number of dimensions rises. The pseudocode for the K-NN algorithm is shown in Table 102.2.

2.3. Statistical analysis

The most used tool for computing mean, F-value, standard error means, significance value, and df is the IBM SPSS. It facilitates speedy data analysis and offers precise details on instances and factors. A relationship with any analysis can be provided more quickly and with less effort. Through charts and graphs, SPSS [16] provides a wider range of possibilities for data analysis. The text size would be the dependent variable in the case of text extraction from photographs, Technology

Table 102.1. Shows that the pseudocode used by the Novel OCR algorithm. The below table represents the pseudo code for Multi-Keyword Scoring Technique. To make this algorithm work first install all the necessary python libraries. Then the model is trained with a dataset in 2 ways, 1) testing/validation data 2) training data. For calculating the accuracy values both testing and training datasets can be considered with 2 different functions

Input: Images and videos (BBC news dataset)
Output: Accuracy of text grabbing.
Step 1: Enhance the image contrast using histogram equalization or other image processing techniques
Step 2: Identify and separate the characters in the image
Step 3: This can be done using techniques such as connected component analysis, thresholding, or stroke width transformation
Step 4: Extract features from the segmented characters
Step 5: These features could include shape, size, and pixel intensity values.
Step 6: Use language modeling techniques to correct any errors in the recognized text
Step 7: Output the final recognized text.

Source: Author.

transfer, Discrete Cosine Transform, whereas the independent variables would be the attributes of the image and the methods and algorithms employed to extract the text.

3. Results

Table 102.1 shows that the pseudocode used by the Novel OCR algorithm. The below table represents the pseudo code for Multi-Keyword Scoring Technique. To make this algorithm work first install all the necessary python libraries. Then the model is trained with a dataset in 2 ways, 1) testing/validation data 2) training data. For calculating the accuracy values both testing and training datasets can be considered with 2 different functions.

Table 102.2 Shows that the pseudocode used by the K-NN algorithm. To make this algorithm work first download all the needed python libraries. Then the model is trained with a dataset in 2 ways, 1) testing/validation data 2) training data. For computing the accuracy ratings both testing and training datasets can be considered with 2 different functions

Input: Images and videos (BBC news dataset)
Output: Accuracy of text grabbing
Step 1: The prediction for a test example is made by finding the K nearest neighbors in the training data and using the majority class label of those neighbors as the prediction for the test example.
Step 2: One key parameter in KNN is the value of K, which determines the number of nearest neighbors to consider when making a prediction.
Step 3: A larger value of K tends to smooth out the decision boundary, while a smaller value of K can lead to a more complex, irregular boundary.
Step 4: Another important aspect of KNN is the choice of distance metric. Common options include Euclidean distance, Manhattan distance, and cosine similarity.
Step 5: K-NN is a lazy learning algorithm, meaning that it does not learn a model during the training phase.
Step 6: It can be computationally expensive to find the K nearest neighbors for each test example, especially when the training set is large.

Table 102.2 shows that the pseudocode used by the K-NN algorithm. To make this algorithm work first gather all the needed python libraries. Then the model is trained with a dataset in two ways, 1) testing/validation data 2) training data. For computing the accuracy ratings both testing and training datasets can be functioned with 2 different functions.

Table 102.3 shows the raw data of comparing both the Novel OCR and K-NN (K-Nearest Neighbours) algorithms.

The value of the standard deviation parameter for Novel OCR is 10.821 and for K-NN is 10.011. Independent sample T-test for distinguishing between Novel OCR (2.307) and K-NN (2.122) standard mean error.

Table 102.5 represents calculations of statistics for independent samples tested between the Novel OCR and the K-NN algorithms. The document frequency value for equal variances assumed is more than not assumed equal variances in accuracy. It shows that there is no statistical significance difference between the Novel OCR algorithm and K-NN algorithm with p=0.254 (p>0.05).

Figure 102.1 denotes bar graphs for accuracy percentages between Novel OCR algorithm and K-NN. The mean accuracy of the Novel OCR algorithm is slightly higher than K-NN. X-axis: Novel OCR vs K-Nearest Neighbor algorithm. Y-axis: Mean accuracy of extraction of information from images and videos with +/- 1 SD.

4. Discussion

The overall accuracy of the Novel OCR algorithm is 81. 95% higher than the overall accuracy of the K-NN algorithm, which is 78. Novel OCR is commonly used for text extraction in a variety of applications, including Document processing of Novel OCR can be used to extract text from scanned documents for further processing [4, 19, 20], such as data entry or text analysis. Text extracted from video clips can provide useful keywords that can reflect the general theme of the video as words have clear, unambiguous meanings. The massive video data set can be searched for essential information via text extraction. Obviously, the text that was taken out of the video image is crucial. Extracted text serves as a crucial indicator of the video's content, making it simple to classify videos. One of the factors of analysis of the video, image analysis and retrieval system is identified as video and image text extraction. The limitations in the existing research regarding text description extraction from image and video captioning is ambiguous grammar and content understanding. The text size would be the factor in the case of text extraction from photographs and videos.

5. Conclusion

In natural language, humans can classify and describe visual scenes with ease. However, programming machines to perform the same work is still a challenge. While machines can detect human activity in movies to some extent, the problem of automatically describing visual scenes has remained unsolved. Even though action identification is a well-researched issue in the computer vision community, automatic understanding of actions, particularly for the intricate and protracted human activities, is still lacking. K-Nearest neighbor algorithm provides an accuracy rating of 81.95% that is less than the Novel OCR algorithm accuracy rating 78.32%.

Abstract: The study compares the Novel YOLO V3 SPP for prediction of malicious applications over SSD method to calculate the access time. G power of 80%, the Novel YOLO V3 SPP algorithm is used to compute the access time using a sample size of (N=25) and a total sample size of (N=50). In terms of data exploitation prediction, the Novel YOLO V3 SPP has an access time that is slower (83.36ms) than the SSD method (80.96ms). With $p=0.480$ (independent sample t-test $p<0.05$), it can be seen that there is no statistically significant difference between the Novel YOLO V3 SPP Algorithm and the SSD Algorithm. Novel YOLO V3 SPP algorithm has a more access time of 83.36ms compared to SSD algorithm access time of 80.96ms predicting vulnerabilities in native applications.

Keywords: Deep learning, novel YOLO V3 SPP (you only look once V3-spatial pyramid pooling), SSD (single shot detector) algorithm, text detection, internet access, national security, vulnerability detection

1. Introduction

Deep learning techniques can be used in Android applications to identify and prevent data leakage and exploitation by detecting and stopping the flow of sensitive data. Correct, deep learning can be used to improve the accuracy of the model in detecting and preventing data leakage, as well as enhance the speed and security of the application [3]. Deep learning algorithms can be trained to recognize patterns and features in data that are indicative of data leakage, and can then be used to identify and stop the flow of sensitive data in real-time. In addition, the use of deep learning can help to improve the overall security of the application by identifying and blocking attempts to access or exploit sensitive data. The most cited article is the SSD model is a well-known and widely-used technique for detecting text in natural images, and is known for its robustness and ability to accurately detect text regardless of its size or position in the image is cited 45 times. This research has had a significant impact on the field of deep learning and has led to the development of practical applications such as license plate recognition and navigation systems. This research aims to enhance the ability to identify and extract relevant text from natural images, with potential applications in various real-world scenarios including vulnerability detection. In contrast, the SSD algorithm has different characteristics compared to Novel YOLO V3 SPP, and it has significantly faster access time. This makes the SSD more efficient and suitable for certain applications that require fast access to data. The aim of this research is to predict vulnerabilities in native applications using the Novel YOLO V3 SPP and find a solution using the SSD algorithm to increase national security.

2. Materials and Methods

The study was conducted at Saveetha School of Engineering, Saveetha Institute of Medical And Technical Sciences in data analysis where the lab is equipped with a high configuration system to conduct a study and get the result. The number of groups considered for the research was two with a sample size of 25. The calculation is obtained by using 80% of the G-power value with a 0. The CVE (Common Vulnerability and Exposures) dataset is used in this study to evaluate the vulnerability scores by analyzing the applications according to their threats and vulnerabilities. The dataset used here helps to detect the vulnerability status, apply the algorithm which is proposed in this paper to this data set, and compare the result with the comparison algorithm. These data are registered through real-time applications and divided into multiple columns which are based on the proposed work. CVE is based on the list of corrupting data applications to increase national security in internet access. In this research, the implementation is carried out using Jupyter notebook, an open-source web application that enables the creation and sharing of documents, including machine learning methods. The code for this research is saved in the Jupyter directory, and the system uses darknet-53 to analyze images in natural scenes. Jupyter notebook allows for the easy execution and organization of code, making it a useful tool for researchers and developers.

2.1. Novel You Only Look Once V3 spatial pyramid pooling algorithm

Novel YOLO V3 SPP (You Only Look Once V3 Spatial Pyramid Pooling) algorithm is the sample preparation group 1 for this proposed work. With Novel YOLO V3 SPP, video footage is quickly and accurately identified as objects using CNNs. The third version of this algorithm was both the speed and precision of detection. An object detection system is designed to quickly identify and classify objects within a dataset by using comparison techniques and processing data in real-time. This allows for efficient detection of large portions of objects. Convolution is used in conjunction with layer convolution to reduce the number of layers in the process. The output of this process is then used for object detection. Based on the fully connected layers and reshaping them to the input image size, the final layer of Novel YOLO V3 SPP predicts an output using internet access. In summary, the primary aim of this research is to enhance the efficiency, accuracy, and speed of object detection along with vulnerability detection. This is achieved through the use of convolutional neural networks and various optimization techniques. Table 103.1 procedure refers to the procedure of the Novel YOLO V3 SPP algorithm to increase national security.

2.2. Single shot detection

SSD is sample preparation group 2. SSD, is a technology that enables computers to recognize and interpret text and images with text. It does this by dividing an image of a text character into smaller sections and analyzing the pixels within each section to identify the corresponding character. This allows the computer to process and understand text and images containing text to increase national security in internet access. SSD algorithm is a technique for extracting features from images that is used in object detection and recognition. However, one of the drawbacks of using this technique is that the quality of the original image may be degraded during the conversion process, which can affect the accuracy and legibility of the resulting text. Another limitation of using SSD is that it can be resource-intensive, requiring a significant amount of computing power to process images. This may be an issue if the amount of text being converted is small compared to the overall size of the image. In these cases, the resource demands of using SSD may outweigh the benefits of using this technique to increase national security. Table 103.2 procedure refers to the procedure of the SSD algorithm.

2.3. Statistical analysis

The IBM SPSS of version 26.0 is used in the statistical software used to compute the standard derivation, mean, and standard error means, mean difference, sig, and F value. Independent variables are the number of installations detected in real time and the dependent variables are access time in application. In this study, an independent T-test analysis is performed [16].

Table 103.1. Procedure for SSD (Single Shot Detector). The SSD algorithm takes the dataset of vulnerability in apps and helps to predict it by using this algorithm

Input: CVE (Common Vulnerability Exposure) Dataset
Output: longer access time
Step 1: Captured image from the natural scene is further divided into scales.   Step 2: Observes the output and predicts the weight.   Step 3: Dividing images in no of scales.   Step 4: The image undergoes the neural networks techniques.   Step 5: Finally, predicting the output by score generation.

Source: Author.

3. Results

The procedure for the Novel YOLO V3 SPP (You Only Look Once) is shown in Table 103.1. Moreover, data is taken from the dataset. Every image in a surrounding natural scene is detected by the novel YOLO V3 SPP. For further testing of the model's data, these values are defined trying to get a faster access time.

The procedure for the SSD is shown in Table 103.2 of this article. To compare the Novel YOLO V3 SPP and SSD algorithm, a dataset is employed. SSD predicts less accurately than Novel YOLO V3 SPP. As a result, the algorithms are used to assess it for suitable access time.

Table 103.3 shows the access time in raw form for both Novel YOLO V3 SPP and SSD.

Table 103.4 shows the N (25), Mean (83.36), Standard Deviation (11.626), and Standard Error Mean values for the Novel YOLO V3 SPP (You Only Look Once) and the N(25), Mean(79.20), Standard Deviation (9.925), and Standard Error Mean values for the SSD Algorithm.

Table 103.5 represents the T-Test values of Statistical Independent samples. The mean difference is 3.720, the standard error deviation is 2.981, and the 95% confidence interval for the Novel YOLO V3 SPP and SSD algorithm. It shows that there is no statistical significance difference between the Novel YOLO

Table 103.2. Procedure for YOLO V3 SPP (You Only Look Once Version3 spatial pyramid pooling). This YOLO V3 SPP algorithm helps to predict the exploited data outside the application in a quick span. And it shows the access value much better

Input: CVE (Common Vulnerability and Exposures) dataset

Output: longer access time

Step 1: First input is a captured natural scene image.
Step 2: It undergoes through the convolutional layers, it uses 1*1 layer which predicts the size of the image.
Step 3:Observing the image and calculating the weights in the image.
Step 4: It has three anchors which are called anchors which predicts the log space.
Step 5: The output is calculated in access time and accuracy of image detecting.

Source: Author.

V3 SPP and SSD algorithm. The access time is computed and is used by the bar graph gain and values.

4. Discussion

The access time of the Novel YOLO V3 SPP has a better significance value of 83. In statistical result values the significance of the Novel YOLO V3 SPP algorithm has less than the SSD significance value of 80.96. The goal of SSD is learning to the accuracy of the predictions made by multiple base learners by combining their individual predictions into a single, more accurate result. The idea is that the combined predictions of the base learners will be more accurate than the predictions of any individual base learner [19]. This approach can help improve the speed at which solutions are obtained and the overall accuracy of the results to increase national security. Finally, the SSD algorithm works well in text detection and provides better access time but not as good as Novel YOLO

V3 SPP algorithm to increase national security along with vulnerability detection. This version of the algorithm has applications in areas such as traffic control and license plate recognition. In addition to potentially improving the accuracy of text extraction, the grid-based approach of the version 3 SSD algorithm may also provide faster access time compared to previous versions. Researchers are working to improve the security and usability of android applications by using SSD to provide accurate and efficient text detection in images, as well as improving access time. The future work is to prove safe and secure usage and longer access time in every application.

5. Conclusion

The prediction of real-time data leakage application in android has been performed by Novel YOLO V3 SPP and the SSD algorithms with different trained detection datasets, by comparing the two algorithms the access rate of Novel YOLO V3 SPP has a more significant rate than the SSD algorithm. The performance and sensitivity are higher in the Novel YOLO V3 SPP (83.36ms) than in the SSD (80.96ms). Loss of data is less in Novel YOLO V3 SPP than in the SSD algorithm.

104 Analysis of vehicle theft detection and enable alert signal using Novel ResNet-50 compared and Lasso regression with improved accuracy

Girish Subash S.[a] and S. Kalaiarasi

Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The goal is to analyze the accuracy of vehicle theft detection using two different machine learning techniques and compare the overall performance of selected classifiers. For this research, neural networks namely Novel ResNet-50 and Lasso regression classifiers are chosen. Materials and Methods: The classifier model is trained with a dataset volume of 80% and 20% is utilized for testing, having sample size 10 for each group under consideration. Result: The selected Novel ResNet-50 classifier improved security to avoid vehicle theft by facial recognition with the accuracy of 97% and LR classifier gained accuracy of 90% with a significance value of 0.000 ($p<0.05$) that was obtained by performing an independent sample test. Conclusion: This research proposal examined face recognition, face recognition theories, face detection, and related studies, as well as reviewed several face recognition techniques. In comparison to the Lasso Regression classifier, Novel ResNet-50 performs better.

Keywords: Vehicle theft detection, machine learning, novel ResNet-50, lasso regression, facial recognition, biometric recognition, theft

1. Introduction

The amount of automobiles on the road and the number of robberies have experienced a spectacular rise [15]. It is impossible to identify the stolen vehicle in such a high-stress situation using conventional techniques like human inspection and RFID-based technology, which are simple to modify and delete. The most common security system in use right now is an authentication system based on biometric sensors and face recognition. It is advised for this research to use machine learning, which solves numerous computational problems in a condensed amount of time [16, 21]. It has uses in the identification of plant diseases, the selection of wholesome foods, and patient health monitoring. The recommended supervised classifier techniques to perform fraud detection with higher accuracy gain. The classification of fraudulent activities from the selected dataset and this study recommended LR, KNN, neural network respectively. The

collecting images and fingerprints of voters to enable secured smart voting systems. The most popular method for quickly producing answers and resolving complex problems is machine learning. In order to distinguish between authorized users and unauthorized users, the suggested system uses ML classifiers in conjunction with a facial recognition system. The major goal is to recognize a person's face even in low-quality images and increase recognition rates.

2. Materials and Methods

2.1. Novel ResNet-50

A CNN classifier with 50 layers called Novel ResNet-50 incorporates jump connections and a residual learning structure [10]. The model consists of a sequence of convolutional blocks that use average pooling, with five convolutional layers in total. To classify data, the model uses a Softmax layer and skip connections to

connect with the previous layer [9]. These skip connections incorporate a neural network to maximize accuracy, and the model presents two mappings.

2.1.1. Pseudocode

Step 1: This involves gathering the necessary amount of data for the dataset. The data should be collected based on the problem statement and the objectives of the study.

Step 2: In this stage, the collected data is prepared for further analysis. Pre-processing involves tasks such as data cleaning, normalization, and feature selection.

Step 3: If any noise or empty spaces are present in the dataset, they need to be removed to avoid skewing the analysis results. This is an important step to ensure that the data is accurate and reliable.

Step 4: Once the data is pre-processed, a suitable classification model needs to be developed and trained. This can involve selecting a suitable algorithm, training, and optimizing the parameters to achieve best results.

Step 5: Finally, the classification process is conducted using the trained model. The aim is to accurately classify new instances based on the features of the data. The classification should be performed with the desired accuracy range, which can be determined based on the problem statement and the objectives of the study.

2.2. Lasso regression

A type of linear regression mainly utilizing shrinkage [12]. The data values shrink on the certain point as mean. It is well suited for models showing higher levels of multicollinearity. It does variable selection and rearranging to improve the prediction accuracy and interpretability of statistical regression models.

2.2.1. Pseudocode

Step 1: The first step involves selecting and loading the dataset to be used for training and testing the ML classifiers.

Step 2: Once the data is loaded, it may require modification to suit the requirements of the proposed approach. This may include data cleaning, preprocessing, and transformation.

Step 3: The next step is to select the relevant attributes and extract the necessary features that are needed to improve the classification accuracy of the ML classifiers. This may involve using techniques such as dimensionality reduction, feature selection, and feature engineering.

Step 4: After the feature extraction process, the ML classifiers are trained using the selected features. The training process involves using the majority of the dataset, typically 80%, to train the model to recognize patterns and make predictions.

Step 5: Finally, the trained classifiers are used to classify new data by making predictions based on the learned patterns. The accuracy of the classifiers is then evaluated using testing data, typically 20%, which was not used during the training process.

2.3. Statistical analysis

The study's independent variables consist of pictures of vehicle number plates that have been selected for verification purposes, while the dependent variable is the numbers and alphabets displayed in the number plate pictures. The study recorded the expected correctness to perform the analysis. The independent sample T-test was conducted to find the significance. The SPSS tool, also known as the Statistical Analysis Program, was utilized to conduct the statistical analysis.

4. Result

To enhance the security system of vehicles parked in public places such as hotels, parking areas, streets, and resorts, this study analyzed and performed automated vehicle theft detection using two classifiers: Novel ResNet-50 and LR. The Python compiler was used to determine the accuracy gain of the Novel ResNet-50 and LR classifiers, which were recorded as 97% and 90%, respectively. The proposed Novel ResNet-50 classifier detected fraudsters' activities on parked vehicles at a high rate, indicating the effectiveness. Table 104.1 displays the accuracy gain of the Novel ResNet-50 and LR classifiers obtained from the Python compiler. Additionally, the confusion matrix of the ResNet50 model is shown in Figure 104.1, while the training and testing accuracy and loss of the

After detecting the license plate from the vehicle, we will extract the license plate number from the image. Then segmented characters from the Input Image which is shown in Figure 104.6. Then segmented characters and their predicted value is shown in Figure 104.7.

5. Discussion

The results of the analysis indicate that the ResNet-50 model outperforms the Lasso model in terms of accuracy, specificity, and sensitivity. The ResNet-50 model achieved an accuracy of 97%, a specificity of 0.98, while the Lasso model achieved an accuracy of 80%. The higher accuracy, specificity, and sensitivity of the ResNet-50 model can be attributed to its deep architecture and skip connections, which enable it to better capture features and minimize information loss during training. On the other hand, the Lasso model is a linear regression model that is commonly used for feature selection and regularization in machine learning. For facial recognition CNN classifier is utilized and it achieved accuracy of 98.75%. The selected features for facial identification are position of mouth, shape of chin, length and width of nose. The selected dataset consisted of 47 face images of different people and it gained a recognition rate of 90%. While the results of this analysis provide useful insights into the performance of the ResNet-50 and Lasso models, it is important to note that they are limited by the specific dataset and task used in the analysis. Further studies may explore the performance of these models on larger and more diverse datasets to obtain a more comprehensive understanding of their strengths and limitations. Additionally, future research may explore the potential of hybrid models that combine the strengths of both ResNet-50 and Lasso models to achieve even higher accuracy and robustness, especially in scenarios where feature selection and regularization are important.

6. Conclusion

This research proposal examined face recognition, face recognition theories, face detection, and related studies, as well as reviewed several face recognition techniques. The proposed Novel ResNet-50 classifier outperformed the Lasso classifier with an accuracy of 97% and 90%, respectively. This is based upon a variety of techniques, including face and license plate feature extraction, morphological modification, edge detection, and image enhancement. In comparison to the LR classifier, Novel Resnet-50 performed better.

105 Detection of cervical spine fracture using DenseNet121 and accuracy comparison with convolutional neural network

Kaviya V. H.[a] and P. V. Pramila

Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The prime purpose is to measure the performance of the models Innovative DenseNet121 and Convolutional Neural Networks in accurately categorizing the presence or absence of cervical spine fractures from CT images: Innovative DenseNet and Convolutional Neural Network (CNN) are the two deep learning models opted for the analysis to compute the accuracy for the dataset "Cervical fracture" which is acquired from kaggle. It contains a sample size of 4,200 CT images. Out of these, 3,800 CT images were allocated for training the model, while the remaining 400 CT images were used for evaluating the model's performance. The estimation of the iteration sample size used a G power of 80% with 95% confidence interval. Ten iterations were performed using the aforementioned models on the experiment. The Innovative DenseNet model achieved an accuracy of 93.64% for distinguishing between the presence and absence of the fracture, whereas the Convolutional Neural Network (CNN) yielded a accuracy of 77.32% The t-test result (p<0.001, 2 tailed) shows that there exists significance amongst the two learning models considered here. This study investigated an approach that contrasted two deep learning models to see which was more accurate in predicting fractures. The results demonstrate that DenseNet121 outperforms convolutional neural networks in identifying cervical spine fractures.

Keywords: Cervical spine fracture, convolutional neural network, deep learning, innovative DenseNet, medical, CT

1. Introduction

A cervical spine fracture is a medical condition characterized by a break or fracture in one or more of the vertebrae in the cervical spine, which is the uppermost part of the spinal column located in the neck. Hence an automated Cervical fracture detection system enabling deep learning models aids in the early detection of the abnormality. Application of deep learning models in therapeutic context demands a blend of improved precision, speed productivity, and applicability which helps in early diagnosis of the cervical fracture. In the previous five years, 987 publications in Researchgate and 1700 articles in GoogleScholar are relevant to the detection of Cervical spine fractures. Various models were incorporated in order to improve the functionalities and performance. Hojjat et al. implemented deep sequential learning technological capabilities to identify cervical spine fractures on CT scans and obtained an accuracy of 71% [12]. Another study used MRIs to detect cervical fractures by using CNN and attained an accuracy value of 92%. The accuracy of Unet models varied from 99. To demonstrate the effectiveness of deep learning in solving this issue, using an ensemble approach, Hojjat and coworkers [9] integrated the ResNet50 and Bidirectional Long Short-Term Memory models. The functionality and performance of the two deep learning models, Innovative DenseNet and CNN are studied to establish which model is more effective and accurate at detecting fractures in the cervical spine.

2. Materials and Methods

This comparative evaluation analysis on Cervical fracture classification was held in the Programming Laboratory of Saveetha School of Engineering' (SIMATS).

The evaluation used two deep learning approaches, Innovative DenseNet and CNN, with a size of (N=10) samples. The experiment was repeated tenfold using the aforementioned technological capabilities. The G-power of 0.8 with 95% confidence interval is used.

The study was performed using HP Pavilion Laptop 14ec with Windows 11 Home had an AMD Ryzen 5 series processor-x64, 8GB DDR4-3200 MHz RAM, a 64-bit OS, and AMD Radeon Graphics. The execution took place on the Google Colab platform.

CT samples (4,200) of cervical spine with size 224x224 were categorized into fracture and normal subjects. The images are enhanced by sharpened and rotation techniques. The dataset was acquired from Kaggle [8]. The two groups namely Innovative DenseNet and CNN were trained on 80% of the cases and evaluated on 20% of the cases.

3. DenseNet121

It is a type of Neural Network in which the layers are linked closely to one another using dense layers as shown in Figure 105.1. DenseNet was evolved to address the declining accuracy produced by high-level neural network's vanishing gradients. The loss of information occurs as it traverses a longer distance between the input and output layers. In the DenseNet architecture, each layer incorporates and passes on information from all previous levels, extending this feature-sharing process. Finally, after a global average pooling step, a softmax activation is applied at the conclusion of the last dense block.

4. Convolutional Neural Network

CNN is a prominent neural network used for object and imagery recognition and categorization. In order to solve problems with image processing, computer vision, and self-driving car obstacle detection, CNNs are used extensively in a number of jobs and activities, such as speech recognition in natural language processing, video analysis, and video encoding. As a result, Deep Learning employs a CNN to recognise objects in a picture. CNNs are widely employed in deep learning because of their significant contributions to these domains, which are rapidly developing and changing.

5. Statistical Analysis

It involves a systematic method for gathering, interpreting, and concisely summarizing data with the goal of facilitating informed decision-making, identifying patterns, and drawing conclusions related to a particular phenomenon or a broader population. The IBM Statistical Package for the Social Sciences version 26

was used to carry out the comparison. The independent variables are fracture and normal CT samples, and the accuracies of the two models are the dependent variables. This test determines whether there is evidence to suggest that the means of the respective populations are significantly distinct.

7. Discussion

In one study, the objective was to distinguish between fractured or unfractured humeri using compressed posterolateral radiographic images of the shoulder in which ResNet-152 convolutional neural network was employed, attaining 95% accuracy, 0. Deep neural

networks are extremely helpful in the pre-classification of clinical diagnoses. 954 was obtained by Kim and others using a variant of the model Inception V3 to predict wrist fractures on axial radiographic images. In contrast to what the majority of other researchers have done, their model looked at the complete radiological image rather than the area of concern that had been clipped. Their research was limited, however, by keeping out the radiographic images with unique forms of projections that seem to be ambiguous for the existence of fractures, limiting a possible use case for its implementation in clinical practice was using thoracic spine Computed Tomography images, as well as lumbar regions to classify, detect, and locate and assess lumbar vertebral fractures. Healthy and unhealthy vertebrae yielded very less accuracy, with an Area Under Curve of 0.5. The sensitivity for compression fracture identification and localization was 0. DenseNet and Convolutional Neural Network are the two deep learning models that were used in this analysis. The small size of the test dataset had an impact on the classification accuracy while testing the model. Developing deep learning models that can fit in faster and train sooner while employing a dataset with better proportions could be the main goal of future research.

8. Conclusion

DenseNet and CNN are the two deep learning models employed, where DenseNet is considerably more accurate than CNN in identifying cervical spine fractures, achieving an accuracy of 93.64% compared to CNN's 77.32%. The results demonstrate that DenseNet performed better than CNN and was more proficient at identifying cervical spine fractures. The suggested approach delivers a wide range of possibilities in medical imaging and is practicable in terms of workflow efficiency. The research shows how deep learning models can be applied to resolve the problem of handling huge datasets with enhanced accuracy. The aforementioned techniques are very effective at improving prediction accuracy and identifying cervical spine fractures, according to the study's results.

106 Recognition of masked face using Visual Geometry Group (VGG-16) algorithm in comparison with Long Short Term Memory (LSTM) algorithm for better detection

P. V. Shriya[a] and W. Deva Priya

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The aim of this study is to address the challenge of innovative face recognition with masks, a pertinent issue since the onset of the COVID-19 pandemic, for the social protection of individuals. The research focuses on the detection of masked faces and their recognition, comparing the performance of the Visual Geometry Group (VGG-16) algorithm with the Long Short-Term Memory (LSTM) algorithm to achieve higher accuracy. Materials and Methods: The study comprises a total of 112 samples, with each algorithm consisting of 56 samples subjected to 10 iterations. Statistical tests are conducted with 80% G Power. The dataset used for the study comprises a total of 2800 images, with 2240 images allocated for training and 560 for testing. These images are sourced from Kaggle.com, specifically from the dataset named CoMask20, as well as from self-obtained images. Results: The Visual Geometry Group (VGG-16) algorithm achieves an accuracy rate of 87.7%, while the Long Short-Term Memory (LSTM) algorithm achieves an accuracy rate of 81.05%. The calculated significance value is 0.001 (p < 0.05), indicating that both algorithms exhibit statistical significance in the context of masked facial recognition. Conclusion: In conclusion, this study establishes that the Visual Geometry Group (VGG-16) algorithm offers higher accuracy when compared to the Long Short-Term Memory (LSTM) algorithm for masked facial recognition.

Keywords: Long short-term memory, visual geometry group, innovative face recognition, mask detection, social protection, covid

1. Introduction

Innovative Face Identification is a technique that aids in the recognition of faces in images. In order to improve facial and identity identification while a person is wearing a mask, this research introduces a novel technique that makes use of machine learning techniques. Before determining the identity of a face, one must first determine whether or not the person is wearing a mask [9, 12]. After thorough observation, it was shown that some of the algorithms did not deliver superior outcomes when recognizing the face behind a mask. This paper describes the vision-based methodology needed to recognize patterns as the face information from a webcam of a computer, for which CNN algorithms are used. This study is an attempt at social protection as

the concern is to detect whether the face has the mask on it as the movement of the face, as well as whether the mask is in the proper position. Figure 106.1 shows the process of face detection with a mask. Due to the inaccurate detection and recognition of a face wearing a mask, there is a research gap. The study aim of this ground-breaking research is to create a system for innovative face recognition comparing the Long Short-Term Memory and Visual Geometry Group algorithms. A selection of the top articles have been gathered from the substantial knowledge and are listed above.

2. Materials and Methods

The Saveetha School of Engineering and Saveetha Institute of Medical and Technical Sciences in Chennai at Cloud

Computing Laboratory were responsible for the study's conception and execution. Both the LSTM and VGG-16 algorithms were taken into account. Clincalc.com is used to compute the sample size. 2800 images total, make up the study dataset, of which 2240 are trained and 560 are tested, which is obtained from Kaggle.com named CoMask20 and coupled with self-obtained images. 56 is the number of samples, and there are 10 iterations total. The sample size was calculated utilizing factors such as a 0. Jupyter Notebook and Google Colab were used to code the requested piece of work. Both machine learning and deep learning require the Windows 10 OS as a platform. For easy access to the code, 8GB of RAM is recommended as the minimum size. The dataset has images with masks and without masks, which is necessary for the training of the entire framework for the research on innovative face recognition with a mask.

2.1. *Visual geometry group (VGG-16) algorithm*

The Visual Geometry Group (VGG-16) algorithm is the type of Convolutional neural networks and performs based upon the task transfer learning method. Its applications are Innovative Face Recognition, image processing, and face detection. It also works with pre-trained datasets. It helps easily in the classification process with 16 layers of neural network. Figure 106.1 describes the architecture of the Visual Geometry Group (VGG16) algorithm which is used for the process of masked facial recognition.

Algorithm

Step 1: Import the dataset and input the weights for the training layers.

Step 2: The data is split for the testing and training.

Step 3: Re-train the images at the output layers with their weights and do feature extraction from an image.

Step 4: The application of the visual geometry group algorithm has been done.

Step 5: At the last step the prediction of the accuracy of the identification of the identity in the live stream.

Step 6: The face identity is found with the bounding boxes which is considered as the output for recognition.

2.2. *Long short-term memory (LSTM) algorithm*

The Neural Network (NN) method named Long Short-Term Memory, is mainly used for the detection of objects and faces. It belongs to the feedback neural network. It functions with data that is organized into a series. Convolutional Neural Network (CNN) architecture can also be combined with it and used in

conjunction with it. Data that can be used for long-term dependence can be stored there.

Algorithm

Step 1: First, the image's face patterns are used as input.

Step 2: Using the patterns of the face's structure, the face is located.

Step 3: From the video stream, pixels must be extracted. Only after the unneeded parts of the face have been removed are the essential parts, such as the eyes, forehead, and brows, taken into consideration.

Step 4: The trained image dataset is run through the Long Short Term Memory algorithm to produce the results.

Step 5: Less inaccurate predictions were made when a mask was used to identify the face. Moreover, the accuracy has increased in comparison to the earlier algorithms.

2.3. *Statistical analysis*

Statistical analysis in this research is conducted using IBM SPSS software. The independent variables include Accuracy, Distance, Volume, Frequency, and the Number of Images. On the other hand, the dependent variables encompass Images, Objects, and Masks. A dataset comprising 2800 images was obtained from the Kaggle website for this study. The significance value, which is known to be 0.001, is utilized in the analysis. The independent variables are sourced from the work of Elliott and Woodward in 2019. To extract key statistical measures such as the mean, median, standard deviation, and standard mean error, an independent sample t-test was applied. In essence, IBM SPSS software is employed for statistical analysis, with a set of

Table 106.1. The following table contains accuracies for recognition of masked face for Visual Geometry Group (VGG-16) and Long Short-Term Memory (LSTM) algorithms

Iterations	VGG-16	LSTM
1	90.35	82.16
2	84.28	87.56
3	91.33	80.42
4	87.16	79.74
5	83.12	80.78
6	89.70	81.37
7	83.90	83.92
8	90.14	81.05
9	86.68	80.58
10	90.58	78.54

LSTM algorithm, the Visual Geometry Group method performs well. The values of the accuracies are displayed in Table 106.1 calculated for the 56 samples for both LSTM algorithm and Visual Geometry Group algorithm. The values of mean of accuracies and the values of standard deviation which have been calculated for both Long Short-Term Memory and Visual Geometry Group algorithms using IBM SPSS are mentioned in Table 106.2. The architecture of the VGG16 algorithm is depicted in Figure 106.1. Figure 106.2 illustrates the output, which represents the identity recognition in an image using the VGG16 algorithm. However, it demonstrates improved accuracy when compared to the Long Short-Term Memory algorithm, which is primarily effective for straight faces. Figure 106.3 showcases the confusion matrix for both the Visual Geometry Group algorithm and the LSTM algorithm. In Figure 106.4, a graphical representation compares the mean accuracies between the Visual Geometry Group algorithm and the Long Short-Term Memory algorithms. The final outcome reveals that the Long Short Term Memory algorithm does not perform as well as the Visual Geometry Group algorithm.

4. Discussion

The study's results indicate that the Visual Geometry Group algorithm outperformed the Long Short-Term Memory algorithm in terms of accuracy. Specifically, when comparing the accuracy of both algorithms, it becomes evident that the Long Short-Term Memory algorithm achieved a lower accuracy rate of 81. In this research, the research offered a new technique for face detection using a mask after comparing the two algorithms and assessing the low accuracy of both methods. With the help of the OpenCV environment, this creative paper has developed a user-friendly device that tracks the individual. It has employed picture capturing and feature extraction to record the webcam's details. The dataset's poor image quality makes it challenging to identify faces when wearing a mask. The difficulty increases with the number of faces detected at once, and the identity recognition accuracy decreases [5, 15]. Coarse images are difficult to be recognized using the LSTM which has become a difficulty in the existing system. Innovative Face Recognition using a mask was difficult to use when the face was not clearly visible. After recognition, it took a long time to get the desired results. A system which recognizes from various face angles and recognizes in night or less lighting is to be evolved is considered as the future scope.

5. Conclusion

The main challenge faced in Innovative Masked Face Recognition is its limited accuracy and detection capabilities. In this study, two different approaches were employed: the Long Short-Term Memory (LSTM) algorithm and the Visual Geometry Group (VGG-16) method. The results indicate that the VGG-16 method achieved a significantly higher recognition accuracy of 87.7%, while the accuracy of the Long Short-Term Memory (LSTM) algorithm was measured at 81.05%. This underscores the superiority of the VGG-16 algorithm in the context of social protection, as indicated by the study's findings.

107 Recognizing and removal of hate speech from social media using Google Net Classifier in comparison with Bayesian Regression for improved accuracy

S. Poorani[a] and G. Mary Valantina

Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The aim of this study is to eradicate hate speech from social media using two separate Innovation Machine Learning (ML) classifiers. GoogleNet Classifier and Bayesian Regression are the most commonly used and recommended algorithms for better understanding of real-time datasets. GoogleNet and Bayesian Classifier is executed with varying training and testing splits for predicting the hate speech from social media. The Gpower test used is about 85% (g power setting parameters: $\alpha=0.05$ and power=0.85). GoogleNet (91.9520%) has the increased accuracy over Bayesian Classifier (86.8700%) with significant difference value of p=0.002 (p<0.05). The accuracy of GoogleNet is better when compared to accuracy of Bayesian Classifier.

Keywords: Bayesian regression classifier, hate speech, innovation, machine learning, population growth, process, technique, social media

1. Introduction

Hate speech is defined as "content that encourages violence against or has as its main goal the incitement of hatred against individuals or groups based on certain attributes, such as race or ethnic origin, religion, disability, gender, age, veteran status, sexual orientation/gender identity." The prohibition of hate speech is motivated by two main considerations: The first and most well-known justification is that hate speech (also known as speech that incites violence against members of a certain race, sexual orientation, or religion) is likely to really cause harm to those who are being targeted ("the incitement to harm" principle). You can download and save social networking apps on your phone or tablet, or you can stream them through your web browser. Social media apps frequently include messaging, photo sharing, and interactive content. Social networking apps can be divided into a number of groups. Facebook, Instagram, Twitter, YouTube, and other platforms are examples.

Deep learning and natural language processing algorithms can detect hate speech on Twitter that is directed towards white people. In this study, two deep learning models are contrasted and compared. A BiLSTM model with white supremacist corpus word embeddings appropriate to the domain is used to extract the meanings of coded phrases and slang first. Second, BERT, a tool of the contemporary linguistic paradigm (Alatawi, Alhothali, and Moria 2021; Sarankumar et al. 2022). The multi-modal approach proposed in this research makes use of feature photos, feature values from audio and text, machine learning, and NLP to identify hate speech in video content [2]. This Research Examines Violent Expression on the Internet Algorithms based on machine learning (SM). Machine learning can categorize abusive language. Analyzing the processes of data gathering, spelunking, feature extraction, dimensionality reduction, classifier selection, training, and model assessment. Words of hate the evolution of machine learning algorithms [7]. The main application of the project is to detect hate speech from social media to reduce the attitude of anarchy and violence toward other people or groups. Detecting hate speech on social media is an area that has been studied for quite some time; a quick search on IEEE Xplore will turn up over 275 papers, and Science direct will provide over 55. With

the use of a well-liked Transformer-based model, this research offers the first Multi-task strategy to exploiting common emotional knowledge to identify hate speech in Spanish Twitter messages. The detection of hate speech is improved across all datasets by emotional intelligence and polarity improvements. The outcomes make it easier to detect hate speech automatically. It will act as a reference point for research on more effective automatic text classification methods. Natural language processing is used by machine learning to classify texts and detect hate speech as well as the SVM algorithm. In the paper, a method to lessen hate speech is mentioned (Plaza-Del-Arco et al. 2021), (Knoll et al. 2019), (B et al. 2022), (Sankaranarayanan and Umadevi 2022; Vianny et al. 2022). Social media hatred harms other people. Race, creed, caste, and religion would suffer. Even unintentional hate speech is filthy. Hate speech was reduced using NLP and ML systems [1, 8]. This Technique utilizes Convolutional Neural Networks (CNNs) and Deep Learning to identify and categorize hate speech in both visual and written forms. This program allows the machine learning system to identify instances of hate speech in visual media. Accuracy of 95.61% and precision of 94.43% [4–6].

Some of the most common drawbacks of using Bayesian Regression: The model's inference process can be time-consuming. If there is a large amount of data available for our dataset, the Bayesian strategy is not worthwhile, and the regular probability approach performs the task more effectively. The proposed model improves identification of hate speech from social media. This study is to improve the accuracy of classification by incorporating GoogleNet and comparing its performance with Bayesian Classifier [3].

2. Materials and Methods

Speech command datasets are used to train AI/ML models for voice recognition. Speech Commands is an audio collection of spoken words that can be used to train and test keyword identification algorithms. The Speech Commands Dataset has 65,000 utterances, each lasting one second and 30 short words. Using Clinccalc.com, the sample size is determined under the following presumptions: 0.05 for alpha, 0.7 for power, and 0.2 for beta. The dataset is divided into two parts: testing data and training data. For both groups, I've taken 20 samples for the training data and 20 samples for the test data. After training the algorithm to assess its accuracy, I split the dataset into train and test sets.

2.1. Googlenet classifier

GoogleNet, a 22-layer deep convolutional neural network, Google Research created the Inception Network, a deep convolutional neural network. GoogleNet can be downloaded a technique that has been trained using the Places365 or ImageNet data sets. The network trained on ImageNet is able to categorize images into 1000 different object categories, including a variety of animals, a keyboard, a mouse, and a pencil. In addition to a variety of animals, a keyboard, a mouse, and a pencil, the network trained on ImageNet is also capable of classifying photos into 1000 other categories of objects.

Pseudocode
Input: Training Dataset
   Output: Accuracy
   Step 1: Start
   Take the data in step two.
   Step 3: Perform for neighbors x in the image.
   Step 4: Complete the neighbors' image.
   Step 5: Normalize the training data.
   Step 6: Define a sequential model.
   Step 7: Utilize "model.add(Layer_type)" to add models of layers.
   Step 8: Import the dataset and read it.
   Step 9: Several strategies are used to remove hate speech and other undesirable items from the dataset.
   Step 10: grouping datasets into classes
   Step 11: Extracting features
   Step 12: Classification is carried out.

2.2. Bayesian classifier

In a Bayesian classifier, the classification is represented by a latent variable that is probabilistically linked to the variables being observed. Following that, the probabilistic model converts classification into inference.

Pseudocode
   Input: Training Dataset
   Output: Accuracy
   Step1: Begin
   Step 2: Read the Training dataset T
   Step 3: Calculate the mean and standard deviation of the predictor variables in each class
   Step 4: Calculate the probability of fi using the density equation in each class
   Step 5: Probability of all predictor variables (f1, f2, f3, ..., fn) is calculated.
   Step 6: Calculate the likelihood for each class
   Step 7: Get the greatest likelihood
   Step 8: Classification of dataset into classes
   Step 9: Feature extraction
   Step 10: Performs classification.

The desired task was developed and implemented using the Python OpenCV application. The test bed for deep learning was the Windows 10 operating system. The hardware configuration used a 4GB RAM and Intel Core i7 processor. A 64-bit system was used. Java was used as the programming language to implement the code. The dataset is being worked on in the background to execute an output procedure for code execution accuracy.

2.3. *Statistical analysis*

SPSS software is used to statistically analyze GoogleNet and Bayesian Classifiers. Among the independent variables are decibels, frequency, modulation, amplitude, volume, and image. Images and objects function as dependent variables. Independent T test analysis is used to assess the validity of both strategies.

3. Results

Table 107.1 compares the accuracy levels of the suggested and established techniques. Table 107.2 displays the group's mean and standard deviation, and the accuracy of the Bayesian Regression and Google Net Classifier techniques was 91.9520% and 3.06905 and 86.870% and 3.03829. The standard error of the Google Net classifier, which was lower than that of Bayesian Regression, was 0.97052.

The results of the independent sample test, which are shown in Table 107.3, demonstrated the wide range of accuracy of the proposed Bayesian Regression and Google Net classifiers. There is a statistically significant difference between the two methods, as shown by the two-tailed p value of 0.002 (p 0.05).

The proposed over chosen input and the standard method's accuracy and mean accuracy calculations are shown in Figure 107.1. The proposed approach outperformed the standard approach, which had a mean accuracy of 86.790%, at 91.9520%.

Table 107.1. GoogleNet classifier obtained accuracy of 96.1% compared to Bayesian classifier having 91.2%

Execution	GoogleNet Classifier	Bayesian Classifier
1	87.1	82.1
2	88.3	83.1
3	89.5	84.6
4	90.4	85.9
5	91.6	86.1
6	92.9	87.6
7	93.7	88.5
8	94.8	89.4
9	95.1	90.2
10	96.12	91.2

4. Discussion

The significance difference of two tailed values of p=0.002 (Two-tailed, p>0.05) found in this research suggests that GoogleNet is superior to Bayesian Classifier. GoogleNet's accuracy is calculated to be 91.9520%, whereas GoogleNet's accuracy is calculated to be 86.8700%.

The primary goal of the GoogleNet model was to classify photographs into a myriad of different categories. The model's structure is made up of 144 distinct layers at 22 depths. The inception module is one prominent component of the network's architecture. The classification process can be accomplished more quickly and accurately by using this module. This is accomplished by reducing the dimensionality and number of training parameters in the input image (Huang et al. 2002). Aiming to better extract context from the input spectrogram, researchers developed two sets of filters, one focused on the temporal domain and the other on the frequency domain. This was inspired by the success of GoogleNet. A concatenated set of the learned features is fed to each layer of the convolutional network. An innovative attention pooling strategy is offered as a subsequent step in determining the most accurate representation of feelings (ISAC Archive). The research outcomes will be applied to the creation of a Twitter categorisation scheme. The Naive Bayes classifier is used by the system to make classification computations, which was built using the js Node framework. According to the experiments (Fatahillah et al. 2017), systems using the Naive Bayes Classifier obtained a best accuracy of 93%. A significant source of uncertainty in the predictions generated by black-box models like neural networks is the lack of transparency into the interpretability and dependability of the predictor. The majority of Bayesian frameworks are used to calculate reliability scores for deep neural networks [3].

The study's drawbacks are related to how long it takes to train GoogleNet, especially when using massive datasets. The system should be broadened to cover more objects while requiring less time to train the data set, according to the study's future objectives.

5. Conclusion

When comparing accuracy, GoogleNet performs significantly better than Bayesian Classifier (91.9520% versus 86.8700%). The data show that GoogleNet outperforms Bayesian Classifier (86.790%) and other methods (91.952%). Compared to Bayesian Classifier's accuracy of 91.2%, Google Net Classifier's score was 96.1%. Comparing GoogleNet to the Bayesian Classifier, the former has a greater mean accuracy and a smaller mean loss. GoogleNet's average accuracy outperforms Bayesian Classifier. Classifier; GoogleNet's standard deviation outperforms the Bayesian Classifier by a small margin. GoogleNet (91.9520%) outperforms Bayesian Classifier (86.8700%) in terms of accuracy, with a significant difference of p=0.002 between the two.

108 Elevating and protecting security for personal health records in cloud storage using tripledes compared over AES with better accuracy

Hemanth Kumar P.[a] and Mahaveerakannan R.

Computer Science Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The objective of the AES algorithm is intended to be the end result of this endeavor to keep cloud-based personal health records secure. Materials and Methods: For the purpose of prediction, we use Triple-Des and novel AES with different training and testing splits. 20 sample sizes were utilized, The ClinCalc software was used to assess the accuracy of the system under supervised learning, in which alpha value is contemplated as 0.5, G-Power value is contemplated as 0.8, and confidence interval of 95%. The value of G-power utilized in this analysis is close to 85% (g-power settings: Alpha =0.05 and powBeta = 0.84 beta = 0.84). Result and Discussion: Comparing Triple-DES (89.96%) to AES (91.38%), As a result, the value of P is higher than 0.05, which means that p = 0.0.60, (P<0.05) statistical significance exists between these two different kinds of programs. Conclusion: This research finds that the Triple-DES classification algorithm is in every essential respect superior than the AES when it comes to enhancing the reliability of storing sensitive information locally while simultaneously storing data in the cloud.

Keywords: AES, cloud storage, innovation, personal health records, symmetric encryption, TripleDES

1. Introduction

Two encryption techniques that are frequently utilized for data security in cloud storage are TripleDES and Novel AES. Information owners must scramble secret information in order to ensure the safeguarding of data security and prevent unauthorized access to data stored in the cloud and in the past. One application of distributed computing that grants control over the data in the cloud is "online data as a service". TripleDES can improve the security and anonymity of cloud-stored medical information, although it may come at the cost of some speed as compared to Novel AES. [7, 8]. In Google Scholar A Modified AES Algorithm for Improving the Cloud Security is the best paper which was founded. PHRs that are stored in the cloud offer patients a simple and quick way to maintain their health information, as well as a way for healthcare professionals to access and update the data as necessary. It is used for data storage and secure communications in Symmetric encryption. In Google Scholar A Modified AES Algorithm for Improving Cloud Security is the best paper which was founded. The primary purpose of the undertaking is to provide best Accuracy for PHRs in cloud. Encryption is just half of cloud storage security for sensitive health data.

2. Materials and Methods

In the Image Processing Lab of the Saveetha School of Engineering and the Saveetha Institute of Medical and Technological Sciences (SIMATS), where the planned research investigation is now being carried out. The authors declare that this document does not require an ethics committee's approval or any special permission. We evaluated the controllers and ran the Gpower software to get the optimal sample size (Bengacemi et al. 2021). Two groups undergo the operation, and their results are compared with one another. Ten representatives are selected at random from each

category. The new triples and innovative AES algorithms are developed with the use of technical analysis software. GPower 3.1's random number generator is used in order to produce samples of size 10 for each of the groups (alpha = 0.05, beta = 0.84 for g-power configuration).

In this study, a dataset from the Kaggle open-access dataset was used. One of the most popular social media networks among experts in information research and artificial intelligence. It allows customers to search for and find the datasets they need, and also offers them a configurable Jupyter notebook environment, a free GPU, and six hours of runtime [12]. The dataset includes information on duplicate, null, and missing values for symptoms associated with the British Job employment agency and innovation. It features 105 rows and 10 columns. The datasets are pre-processed to remove duplicate and null items using the tools that Microsoft Excel provides. The dataset only contains numerical forms, thus there is no need to do.

The Java Development Kit was used to design and build the proposed project. The performance of deep learning was evaluated using the operating system known as Windows 10. A Ryzen 5 Processor and 8GB of RAM made up the hardware configuration. This was a 64-bit system. In order to put the code into action, the Java programming language was used. The collection is being worked on to execute a revolution in symmetric encryption, which involves the execution of new code.

2.1. Triple-DES description

Triple DES is an eight-layer convolutional neural network. A prototype of the system that has already been trained on over a million images is available in the ImageNet database. In addition to multiple animal classes, the fully convolutional network can also classify images into the categories of a keyboard, mouse, and pencil. "Triple DES" Krizhevsky did a lot of the heavy lifting in developing the system. It is a Convolutional Neural Network or Novel AES that was published in collaboration with Geoffrey Hinton, the PhD adviser of Krizhevsky and Ilya Sutskever.

Pseudocode:
```
DESEncrypt(data, key):
# Initialize variables for encryption ciphertext = ""
# Perform encryption with key ciphertext = encrypt(data, key) return ciphertext
TripleDESDecrypt(ciphertext, k1, k2, k3):
# Initialize first decryption
plaintext = DESDecrypt(ciphertext, k3)
# Perform second decryption with k2
plaintext = DESDecrypt(plaintext, k2)
```

```
# Perform third decryption with k1
plaintext = DESDecrypt(plaintext, k1)
return plaintext.
```

2.2. Blowfish description

Blowfish is commonly used in software applications, including disk encryption and secure communications protocols. The design of the algorithm is based on the concept of "Feistel networks" which make it highly resilient against differential and linear cryptanalysis.

Pseudocode:
```
BlowfishEncrypt(input, k1, k2, k3):
# Initialize key schedule with k1
keySchedule = keyExpansion(k1)
# Perform initial encryption round with k2
ciphertext = encryptionRound(input, k2, keySchedule)
# Perform additional encryption rounds with k3
for i in range(1, 16):
ciphertext = encryptionRound(ciphertext, k3, keySchedule)
return ciphertext.
```

2.3. An examination of the statistics

When conducting statistical analysis, the SPSS application is typically utilized Triple DES and Novel AES. There is no correlation between any of these quantities (image, things, proximity, wavelength, modulation, amplitude, volume, or decibels). In this context, the photos themselves are the dependent variable in this study. An impartial evaluation using the T-test is conducted to compare the two methods' reliability.

3. Tables and Figures

4. Results

The anticipated accuracy of Novel AES and the actual accuracy of Novel AES are shown in Table 108.1. Table 108.1 describes the accuracy and analysis of the AES and DES algorithms using a sample size of ten for each method. Table 108.2 shows the average accuracy of Triple-DES and Novel AES. The results of an independent sample T test are described in Table 108.3, which compares Triple-DES and the Novel AES algorithm, revealing a significant value of 0. Figure 108.1 presents an examination of the reliability of the two methods, the Triple-DES and Novel AES algorithms. The average and standard deviation for Triple-DES are 1. Loss occurs even when the quintuple, the values for the mean of the standard deviation and the variability in the mean of the Triple-DES are 1. 95542 and a conventional variance around the mean for Triple-DES is 3. Loss measures are visually compared and contrasted between the two algorithms, Novel AES and Triple-DES. 38% accuracy of Novel AES classification to the 89.

5. Discussion

In support of this study, a comparative investigation of several algorithms for detecting dementia showed that the Novel AES classifier was the most effective [3]. Methods and components Classifiers for Triple-DES and Triple-DES are applied to 40 MRI brain

data sets in order to detect dementia. According to the outcomes of the MATLAB simulations, the Triple-DES classifier has a detection rate of 96.3% and an accuracy of 92.2% reached a level of accuracy that was statistically significant Symmetric encryption was used for this research, and the Triple-DES algorithm was shown to be superior to the Triple-DES method in detecting dementia. It is possible to use AI methods in healthcare to improve the precision of diagnoses. The goal of this research is to create a system that can function independently and is based on EMG for identifying PD-related neuromuscular impairment. Data from the ECOTECH project is utilized for an experimental investigation, and the Accuracy. To oppose this study, Researchers examined the two algorithms in cloud storage to see which one provides the highest level of correctness; in this case, the Triple-DES approach proved to be superior. The Triple-DES cipher has a serious problem in that it can only encrypt plaintext that is up to 64 bits in length. To compensate for the low key length of the previous standard DES, the DES cypher is applied to each data block three times in the new standard, thus the name "Triple-DES".

6. Conclusion

This study concludes that when it comes to cloud data sharing, especially sensitive data, the Novel AES predictor approach seems fundamentally superior than the Triple-DES. The Novel AES gets a 91.38% accuracy rating, whereas Triple-DES only manages an 89.96% grade. Based on the findings, it appears that Novel AES performs more effectively than Triple-DES by a margin of 0.60 (mean=87.0580 vs. mean=83.9880).

109 A novel logistic regression algorithm compared with the random forest algorithm to improve the accuracy of predicting crashes in automated driving system cars

G. Rakesh[a] and J. Chenni Kumaran

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: An autonomous driving system car accidents prediction for enhancing accuracy using Novel Logistic Regression algorithm technique was compared to the prediction accurateness with Random Forest algorithm Technique. To predict autonomous driving system car accidents on NH highways by Machine Learning (ML) methods such as the Novel Logistic Regression algorithm (n=10) and the Random Forest algorithm (n=10). The dataset's G-Power value is 80%, and a sample size of 20 can be analyzed. Implements the dataset through a Random Forest algorithm according to the analysis result the accuracy rate (76.03%) outperformed Novel Logistic Regression terms of accuracy (80.92%). The autonomous sample T-test was conducted for these algorithms, and the resulting P value is 0.001 (P<0.05), indicating statistical significance difference between the Random Forest algorithm and the Novel Logistic Regression algorithm. The Random Forest algorithm has a accuracy of 76.03%, which is lower than the Novel Logistic Regression technique's yields of 80.92%.

1. Introduction

In fact, the majority of accident reports involving Self Driving System cars indicate that the primary blame should lie with the human drivers [1]. This study focuses on an accident caused by an ADS automobile or Self Driving System due to a malfunction and uses to estimate the number of injured individuals and the amount of damage. As technology advanced, a variety of Autonomous cars races were arranged to match the performance of the self-driving system built by various institutions and assessed using task-driven approaches. If such mistakes are not addressed appropriately, they inflict significant harm to the public and property. Because automated driving systems skill is not yet completely dependable, the humanoid motorist must take charge of the driving process, supervising and monitoring the driving tasks when the autonomous cars system fails or has limited performance potential. To assess the autonomy of the self-driving system in terms of mobility control, motion planning, and situational awareness, presented a three-dimensional intelligent space analysis methodology. Compared the performance of the measured Automated Driving System under dangerous settings to human driving behavior. The comparison of machine and human intelligence has become a research focus since the creation of robots. The degree of humanoid driving of Autonomous cars has drawn increased attention as a typical representation of intelligent robots [5]. As a result, this artifact investigates the implications of the fact that accidents involving self-driving automobiles would no lengthier be affected by humanoid error, but rather by a system breakdown [21, 26]. It should be

mentioned that one of the most important issues with a completely autonomous car or self-driving system is how people will interact with it.

2. Materials and Methods

In this study, one was formed for Novel Logistic Regression and the other for K-Nearest Neighbors. The suggested method practices a whole of each with a sample size of 20, G-power having 80% from the dataset to compute the software accuracy value and the approximation using a clinical calculator. The independent variable is the script file that was used as input for the forecast model and is reliant on the variable prediction output displayed in the study.

The dataset may be obtained from the open source access website kaggle (Automated Driving Crashes Database), which is utilized for software effort estimation in order to regulate the accuracy of Novel Logistic Regression vs the Random Forest technique. The open source information is made up of rows and sections. On a Windows 11 computer, this software effort assessment of precision was produced using the Jupyter notebook application. The suggested system employs two sets of algorithms: Novel Logistic Regression and random forest, where this algorithm is close-fitting into a dataset that is a verified and qualified model for the process of assessing software effort where cost and time estimation are known.

2.1. Novel logistic regression algorithm

This form of statistical model, commonly known as a Logistic Regression model, is extensively used in predictive analytics and categorization. Logistic Regression determines the likelihood of an event, such as person alive or dead, based on a given dataset of independent factors [9]. Given that the outcome is a probability, the range of the dependent variable is 0 to 1. The logistic formula is used to translate the likelihood of success split by the chance of failure in Novel Logistic Regression.

$$logit(pi) = 1/(1+ \exp(-pi)) \tag{1}$$

$$\ln(pi/(1-pi)) = Beta\_0 + Beta\_1*X\_1 + \ldots + B\_k*K\_k \tag{2}$$

logit(pi) - Dependent variable
X - Independent variable
Maximum Likelihood Estimation is widely used to estimate beta models. (MLE)

In the Logistic Regression equation (1), where X has been the independent variable, Logit(pi) is in fact the dependent value. MLE is one of the most popular techniques for determining the beta variable, or parameter, in this model. This approach evaluates various beta values frequently to find the best fit for the log chances and after each of these cycles in equation (2), the likelihood function is generated, and the goal of logistic regression is to optimize this function to obtain the most precise constraint assessment. After determining the optimal coefficient (or coefficients, if there are multiple independent factors), all probabilities at each measurement may be computed, recorded, and added to provide a forecast probability.

The procedure is as follows:-
1. Obtain a dataset
2. Train a classifier
3. Make a prediction using a classifier of this type.
   Input: Training data
   Step 1: For i=1 to k
   Step 2: For every occurrence of training data d_i
   Step 3: Set the regression's goal value to
$$(Z_j) = \frac{Yi - p(1|dj)}{[p(1|dj)(1-p(1|dj))]}$$
   Step 4: Initialize instance d_j weight to $[p(1|d_j)(1-p(1|d_j))]$
   Step 5: Finalize a (F_j) to the data with class value (Z_j) & weights (W_j)
   Step 6: If P_{id} is more than 0.5, assign (class label:1) otherwise (class label:2)

2.2. Random forest algorithm

A Random Forest Method is a popular guided machine wisdom technique for uses such as classification and regression. We are aware that a forest is made up of numerous trees, and that the more trees there are, the more sturdy and strong [22]. Similarly, the bigger the number of trees in a Random Forest Algorithm, the better its accuracy and problem solving capacity. Random Forest is a classifier that takes the average of multiple decision trees useful to numerous sections of a particular dataset to increase the predicted accuracy of that dataset. It is based on the idea of supervised learning, which is the process of merging numerous models to address a challenging problem and improve the performance of the model.

The following pseudocode used to describe how the Random Forest Algorithm works:
   Input: Training data
   Step 1: For a given test, predict and record the results of each decision tree (D Tree) that was randomly built data.
   Step 2: Determine the total number of crashes in ADS cars for each class.
   Step 3: Designate the result class as the majority class.
   Output: Final predicted class.

To test and train the dataset for autonomous cars or self-driving systems, the proposed model, we used a Juypter notebook and IBM SPSS statistics software

to predict the graph and calculate the mean value for the input data. To get a good percentage of the rate for algorithms that use machine learning, we also used G-Power software to compute the pretest and pretraining for the algorithm. For the implementation and execution of the algorithm on this suggested system, we chose the 64 bits Windows X operating system, 512 GB of SSD storage, and 8 GB RAM.

2.3. Statistical analysis

The Autonomous cars or Automated Driving System analysis was completed using open source software with a trial version of IBM SPSS version 21 statistic software [17] with factors that could be taken from the dataset, including injSeverity, ageOFocc, ads_version, and some subordinated factors like weight, dead, type, vin, and year Veh. For both algorithms, the existing calculation was completed with a cap of 10 iterations, and we noted the accuracy with standard deviation analysis and T-tests in SPSS.

3. Results

The Novel Logistic Regression Algorithm achieved an accurateness of 80.92% and the Random Forest Algorithm had an accurateness of 76.03% when forecasting the number of injuries caused by the failure of an Automated Driving System in a car, using Jupyter Notebook and an existing dataset.

Table 109.1 This comparison evaluates the predictive accurateness of the Novel Logistic Regression Algorithm and the Random Forest Algorithm. The Novel Logistic Regression Algorithm has an accuracy of 80.92%, while the Random Forest Algorithm has an accurateness of 76.03%.

Table 109.1. This comparison evaluates the predictive accuracy of the Novel Logistic Regression Algorithm and the Random Forest Algorithm. The Novel Logistic Regression Algorithm has an accurateness of 80.92%, while the Random Forest Algorithm has an accurateness of 76.03%

Sample (N)	Logistic Regression Accuracy in %	Random Forest Accuracy in %
1	76.98%	72.48%
2	77.98%	73.88%
3	78.65%	74.48%
4	79.33%	75.88%
5	80.92%	76.03%
6	81.05%	77.33%
7	82.45%	78.44%
8	83.22%	79.33%
9	84.02%	80.56%
10	85.33%	81.59%

Table 109.2 The mean accurateness of the Novel Logistic Regression Algorithm is 80.9240, while the mean accuracy of the Random Forest Algorithm is 76.0300. The standard deviation and standard fault means is displayed in the table below.

Table 109.3 The independent sample T-Test was conducted on two groups to compare the overall categorization of the accurateness value. Hence the P value is 0.001 (p<0.05) for there is a statistical significance difference between these two algorithms.

In Figure 109.1. The average accurateness of software estimates was calculated using the Novel Logistic Regression Algorithm and the Random Forest Algorithm. The Novel Logistic Regression Algorithm had an accurateness of 80.92%, while the Random Forest Algorithm had an accurateness of 76.03%. The Novel Logistic Regression Algorithm had a higher accurateness than the Random Forest Algorithm.

4. Discussion

According to the results of the study, the Novel Logistic Regression Algorithm has a greater accurateness rate of 80.92% than the Random Forest Algorithm, which has a projected accuracy of 76.03% in the application. Hence the P value is 0.001<0.05 for there is statistical importance difference between the Novel Logistic Regression Algorithm and Random Forest Algorithm.

Suppose the accuracy rate in the previous model is low due to lack of information. We learned from this investigation that there is a lot of value variance, making it challenging for the machine learning model to remember all of the unique parameters [18]. So by reducing the parameters and taking important data

while processing in machine learning we are able to improve the accuracy rate [15]. Autonomous cars were never at fault, although they were regularly affected from behind when making turns, braking, and accepting gaps [10]. Self Driving System car side accidents were associated with passing vehicles and lane maintenance activities [2]. Unusual events also provided new insights. At present moment, it is impossible to determine ADS collision rates with confidence.

The model limitations include that ADS crash prediction is a difficult task since in recent years, many manufacturers have been creating ADS cars, and failures have happened in many locations, causing accidents, particularly on national highways [14]. The major opposition of ADS is it works on a limited speed of 50km/hr as per car if it crosses more than limited speed then the ADS can control speed and come to fixed speed but it may lead to an accident [7]. This model is only for educational reasons and to verify and forecast the accuracy level of algorithms to improve them, not for use in real life. The suggested study can anticipate collisions and injuries caused by ADS cars in the future. These predictions might be used to predict the ADS crash using previous data and trends.

5. Conclusion

This research examined the expected accuracy of two algorithms, Random Forest and Novel Logistic Regression. In the evaluation of product exertion the Novel Logistic Regression Algorithm's projected accuracy was higher (80.92%) compared to the Random Forest Algorithm (76.03%). Because of this, the Novel Logistic Regression Algorithm is extra accurate than the Random Forest Algorithm.

110 Analysis of machine learning techniques for moisture prediction using random forest and logistic regression to improve accuracy

Jaswanth M.[a] and Mahaveerakannan R.

Computer Science Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: In comparison to Novel Random Forest, Logistic Regression predicts moisture more accurately. To determine the most crucial input components for the job at hand. The technique may be used for feature selection and data analysis and can assist in discovering the variables that are most pertinent to the output variable by producing feature significance ratings. Materials and Methods: For moisture prediction, Logistic Regression and Novel Random forests are used with different training and testing splits. The study included 290 samples; ten people were used as the sample, and the results were as follows different training utilizing the innovative random forest and logistic regression. For identity-based integrity auditing, testing splits are carried out using various training and testing splits. About 85% of the Gpower test was run (gpower setup parameters: 0.05 and 0.85). Result and discussion: Compared to Logistic Regression (93.73%), utilizing the innovative random forest (95.61%) possesses greater accuracy along with a considerable value when two-tailed ($p > 0.05$) compared with Logistic regression. Because of this, a statistically significant difference can only be established if the P value is greater than 0.05 (p 0.05) between two algorithms. Conclusion: In conclusion, both Logistic Regression and Random Forest are effective machine learning methods for predicting moisture. With its ability to handle high dimensional data and resistance to overfitting, Random Forest is a reliable ensemble technique that can be used to forecast continuous moisture values. Logistic regression is a quick and effective technique that can be applied to binary classification problems, making it appropriate for predicting binary moisture values like dry or wet.

Keywords: Innovation, logistic regression, machine learning, moisture prediction, technique, novel random forest

1. Introduction

Moisture prediction is a major issue in many industries, including agriculture, food processing, and construction. Two popular methods are random forest and logistic regression. The technique is based on the hypothesis that a powerful predictor can be produced by integrating a large number of weak decision trees. Moisture prediction is a major issue in many industries, including agriculture, food processing, and construction. Machine learning methods are now much more frequently used for moisture forecasting [15, 21].

Two popular methods are random forest and logistic regression. The ensemble learning method known as Random Forest uses numerous decision trees to produce predictions. The method is based on the idea that by combining numerous weak decision trees, a strong predictor can be created. Wildfire risk can be dramatically increased by moisture prediction conditions. Plants and trees wither and die due to a lack of precipitation, an increase in pest infestations, and diseases, all of which are connected to dryness and function as a catalyst for wildfires. This research contrasts

when compared to Logistic Regression, the efficacy of Novel Random forests is significantly higher, showing that classification accuracy can be increased.

2. Materials and Methods

On this project, there has been collaboration from a number of different departments and institutes, including the Machine Learning Lab, the Department of Spatial Informatics, the Institute of Computer Science and Engineering, the Saveetha School of Engineering, and the Saveetha Institute of Medical and Technical Sciences SIMATS is the study location for the proposed work. The two groups were chosen for the investigation. On the other hand, the approach known as the Random Forest method is utilized by Group 1. The number of sentences used to accomplish the summarizing procedure varies for each sample. All of the text data needed to conduct this study was gathered from a variety of open sources, including news articles, blogs, studies, etc. [7, 8]. A portion of the text is also drawn from a pre-made dataset that the transformation library gave after working on the text and making the findings available to the public [7]. The needed operations are created and executed using Python OpenCV. The hardware consists of a twelve-gigabyte random access memory pool and an Intel Core i3 processor. In the programming, the libraries numpy and matplotlib were utilised. From the kaggle website, 30% of the dataset is utilised for testing and 70% for training.

3. Random Forest

Description: Problems involving classification and regression are tackled using a machine learning technique known as random forest. The final forecast is produced by merging the forecasts of various different decision trees due to the use of ensemble learning. Many decision trees are trained in a random forest model utilizing diverse subsets of the training data. Each tree produces a prediction based on the properties of the input data, and the random forest model combines all of the tree forecasts to provide a final prediction.

Pseudocode:

Data, number of trees, and number of features function of train random forest

If forest = [] for I in range(num trees), then:

Using a replacement sample, sample a subset of the data: sample with a substitution (data)

Choose a subset of the features with features = select features(num features)

Use the sample's selected features to create a decision tree.

Add the trained tree in your forest. The trained decision tree is the tree (example, features).

Append(tree) return in the forest

3.1. Logistic regression algorithm

Description:
An example of a computer Classification and regression learning methodology problems is the Decision Tree. With the provided information, it creates a model of decisions that resembles a tree. A decision tree model divides the incoming data into progressively smaller groups in accordance with a set of rules. A choice is taken based on the importance of a feature in the data at each level of the tree, and the tree branches into two or more paths depending on the result of the decision. Until the tree reaches a leaf node, which stands for a forecast, the technique is repeated.

Pseudocode:

```
function logistic_regression(X, y, alpha, num_iterations):
# Initialize the weight vector with small random values
w = random_small_weights(X.shape[1])
# Repeat for a fixed quantity of iterations
range(num iterations) for I:
# Repeat each training example in a loop
j in the range (X.shape[0]):
#predict the likelihood that the sample falls under the positive category
p= predict_probability(X[j], w)
#calculate the error between the predicted probability and the true label
Error = y[j] - p
#Update the weights using the gradient descent update rule
W = w+ *error * X[j]
return w
```

3.2. Statistical analysis

It is the IBM SPSS tool that is applied in order to carry out the statistical analysis procedure. Using SPSS software, novel random forest and logistic regression statistics are analyzed. Decibels are independent variables, as are images, objects, distance, frequency, modulation, amplitude, volume, and decibels. After time-fine-tuning the performance of the decision tree approach was much better than that of the random forest algorithm when tested with data that was collected independently. The significance threshold is set at $p = 0.05$ (single tailed). Rapidity, prediction, and accuracy are all interdependent.

4. Tables and Figures

Table 110.1. Accuracy and analysis logistic regression of and random forest

Sample Size	Random Forest Accuracy (%)	Logistic regression Accuracy (%)
153	86.90	84.21
179	87.40	85.59
185	88.70	86.48
199	89.10	87.77

5. Results

Anaconda Navigator was used with a sample size of ten in order to conduct an analysis of the proposed Novel Random Forest and Logistic Regression at a number of different stages. Table 110.1 displays the estimated accuracy for new random forest and logistic regression. Ten data samples are needed in order to produce statistical data and the necessary loss values that might be utilized to spark new strategies for each tactic. According to the findings, Logistic Regression had an accuracy of 93.73% on average, while Novel Random Forest had an accuracy of 95.61% on average [8].

Table 110.2 demonstrates the findings of the tests of mean accuracy performed on logistic regression and novel random forests. When compared to Logistic Regression, Novel Random Forest's mean value is better, Both having a standard deviation of 2.99345, whereas the other has a standard deviation of 3.11332 [1,8].

Table 110.3 An insignificant value of 0.236 (Single tailed, P value of 0.03<0.05) is revealed by the following is a list of the conclusions drawn from an Independent Sample T Test carried out on Novel Random Forest and Logistic Regression: [19].

Figure 110.1 contrasts Novel Random Forest with Logistic Regression's accuracy, which is somewhat equivalent to mediocre. A better degree of accuracy is achieved by the Logistic Regression classifier in comparison to that of the Random Forest classifier, as shown by that graph.

The averages, standard deviations, and meaning of the standard error for the novel random forest are 91.0810, 2.99345, and 0.94661, correspondingly. For logistic regression, the corresponding averages, standard deviations, and standard error means are 89.0750, 3.11332, and 0.98452, respectively. The mean, standard deviation, and standard error mean loss values for the Novel Random Forest are 8.9190, 2.99345, and.94661 respectively. On the other hand, the mean loss value for the Classic Random Forest is 8.9190. The value for the mean of the logistic regression for the Random Forest is 9.9250, while its standard deviation is 3.11332 and its standard error mean is 98452.

For both methods, it offers the mean, standard deviation, and standard error mean of the group statistics as well as their respective values. The standard deviation and mean are also presented classification of the two approaches for calculating the chance of loss's visual comparison, Logistic Regression and Novel Random Forest [12]. This demonstrates that the accuracy of 91.5455% that was attained by employing a novel Forest is significantly higher than Logistic Regression Classifiers accuracy of 90.6155%.

6. Discussion

Given that the (single-tailed, p>0.05) significance value for the current study is 0.236, it is possible that Novel Random forests may be more efficient than Logistic Regression. The book Random Forest is responsible for an accuracy of 90.615% of the predictions made as opposed to the Novel Random Forest 91.5455%. In the investigation we carried out for this project, the innovative algorithm Random Forest performed significantly better than others. To deliver superior results rapidly, it makes use of supervised algorithm patterns and distillation employs 40% fewer parameters than a typical Random Forest and is 95% more efficient. The calculated values for the Logistic Regression average, inaccuracy in both the standard deviation and the standard mean are 89.0750, 3.11332, and.98452, respectively employing specifically created diagnostic items, a supervised learning technique that assessed the viability of the Logistic regression and Random Forest models.

To support my project The effectiveness of coupled machine learning models and ensemble methods to forecast drought conditions in Ethiopia Awash River Basin was examined in this work and the similar finding are [5, 9, 11] and opposed finding are [15, 17, 18, 21]. This study investigated the viability of building an accurate artificial neural network and supporting vector regression models for drought prediction using wavelet transformations in combination with bootstrap and boosting ensemble approaches. When employed as a pre-processing method, wavelet analysis improved drought forecasts. The Standardized Precipitation Index, which in this example has values of 3, 12, and 24, represents both short- and long-term drought conditions, is a meteorological drought index that was projected using the models mentioned earlier. RMSE, MAE, and R2 were used to innovate the outcomes of each model. The prediction results indicate that using the boosting.

The limitations of this study indicates that training Novel Random Forest takes a very lengthy time, especially for huge datasets. Extending the system to accommodate one of the project's future goals is to train the data set with less time and more items.

7. Conclusion

This study concludes that Novel Random Forest machine learning can produce results that are more precise. In the novel random forest, it would appear that the classification algorithm is far more effective than Logistic Regression. Whereas the accuracy of Logistic Regression is 93.73%, that of Novel Random Forest is 95.61%. With a significance threshold of 0.236, the analysis shows that Novel Random Forest outperforms Logistic Regression (mean=90.07).

111 A comparative analysis of the question and answer capabilities with the BERT token model algorithm compared with the Novel Roberta token model algorithm for improved accuracy

Bharath[a] and Mahaveerakannan R.

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The main innovation objective of the current study is to evaluate the text summarization capabilities of the Roberta algorithm, compare it with the bidirectional BERT algorithm, and determine the accuracy and performance of both algorithms Text summarization and file transfer workflows are performed using the transformers pretrained models. To achieve a 95% confidence interval for our investigation the corpus of at least 10–20 pages is taken, and the operations are performed on that copus. In the same way, 30 sets of the corpus are taken and divided into two groups. The two groups were BERT and Roberta training algorithms (0.05 and 0.2 respectively), with G power values of alpha and beta, and a total of 10 sample sizes. Both algorithms were compared for their accuracy and speed in their performances. The proposed system found that the Roberta algorithm for summarizing text has a high level of accuracy of 95.1%. The significance value for performance and loss is 0.000 Hence, the P value is less than 0.05 (P<0.05) statistical significance exists between these two algorithms. 10 sample sizes each with G power values of 0.80% for Alpha and Beta The study showed that the Roberta method was more accurate and took less time than the BERT method. The study shows that Roberta is more performant than BERT with fewer parameters. BERT has predicted the tokens independent of each other whereas Roberta being auto regressive in nature, predicted all the tokens in sequence. Novel Roberta uses BERT's 12 layer and 24 layer architectures.

Keywords: Bidirectional, corpus, encoding, innovation, masked language modeling, masked language, novel roberta, training

1. Introduction

Summarization of text data Bidirectionally generally involves the process of summarizing the documents thereby reducing the amount of data which gets as a result. In the practical world, a huge number of logs and textual data is generated every often and it's not possible to read the documents manually. Masked Language Modelling is the process of hiding a few words and using BERT to predict the masks. Even search engines like google, Bingo use text summarization techniques in their existing algorithms to crawl the training model data available on the internet and present the most accurate data as highlighted. The information that is available to search engines is because of the metadata that we include in our websites, based on that the search engine is able to get the information and perform summarization techniques to show the most valuable content as a highlighted item. The most used algorithms these days are quite a few and in this study, we compare the Roberta Masked Language Modelling algorithm with the Bidirectional BERT algorithm. We analyze the total time taken by each of the algorithms and also manually check the accuracy of each of the results given by two algorithms and compare which has the highest accuracy. The BERT algorithm may

also be used to create systems that answer questions. The shortcomings of the current method highlight the model's tokens' erroneous categorization and summarization [6]. The purpose of the study is to demonstrate that innovative Roberta outperforms the BERT approach in more than 20 distinct tasks and produces results that are much more accurate.

2. Materials and Methods

For the study, the two groups were determined. The BERT algorithm is in Group 1, while the Roberta algorithm is in Group 2. We run the algorithms on these text corpora using the 10 sets of 10 page corpora.

For our analysis, a total of ten different sample sizes with datasets [7] were conducted to reach a 95% confidence level. These sample sizes were each carried out using G power Alpha 0.05 and Beta 0.2. The number of sentences used to accomplish the summarizing procedure varies for each sample.

The training model data for this study, which included news stories, blogs, papers, and other materials, was all acquired from a variety of public sources. Also, some of the text was taken from a pre-built dataset made available by the transformers library. The text had already been examined using this dataset, and the results had been made available to the general public.

2.1. Pseudocode for Bert

```
m1 = 'distilbert-base-uncased'
    m2 = 'distilbert-base-uncased-distilled-squad'
    c = 'The United States Of America has recently
revealed the statistics of covid cases and shockingly approximately 70k confirmed cases and 30k deaths, which is higher than any other nation in the world has shocked everyone. However President has said that some states would open despite rise in cases'
    question = "What was President Donald Trump's prediction?"
    encoding = tokenizer.encode_plus(question, context)
    input_ids, attention_mask = encoding["input_ids"], encoding["attention_mask"]
    start_scores, end_scores = model(torch.tensor([input_ids]), attention_mask=torch.tensor([attention_mask]))
    ans_tokens = input_ids[torch.argmax(start_scores): torch.argmax(end_scores)+1]
    answer_tokens = tokenizer.convert_ids_to_tokens(ans_tokens, skip_special_tokens=True)
    print ("\nQuestion",question)
    print ("\nAnswer Tokens:")
    print (answer_tokens)
    answer_tokens_to_string = tokenizer.convert_tokens_to_string(answer_tokens)
    print ("\nAnswer:",answer_tokens_to_string)
```

2.2. Pseudocode for Roberta algorithm

```
m = 'deep set/roberta-base-squad2'
    nlp = pipeline('qa',model=m,tokenizer=m)
    qa_i= {
    'q': 'Why is conversion of models so important?'
    'context': 'Ability to convert between Framework
For Adopting Representation Models and transformers gives much more freedom to user and accessibility'
    }
    res = nlp(qa_i)
    m = AMFQA.from_pretrained(m)
    AutoTokenizer.from_pretrained(m)
```

Roberta is a cheap and lightweight Transformer based model using the BERT architecture. Knowledge distillation is performed during the pre-training phase to reduce the size of a BERT model by 40%.

2.3. Statistical analysis

Statistical Software used in this research study was SPSS (Statistical Package for the Social Sciences). Independent variables in the data set are corpus, paragraph, pdf documents, word documents and size of words. Dependent variables are accuracy and time consumption. Independent sample t-test has been carried out for analysis [7].

3. Tables and Figures

Table 111.1. Comparison between Roberta and BERT algorithm N=10 samples of the dataset with highest accuracy of respectively 95.1 and 79.1 respectively

Sample (N)	Dataset Size	Roberta accuracy in %	BERT accuracy in %
1	950	95.1	79.5
2	940	92	78.2
3	930	90.3	77.8
4	920	90	77.2
5	910	89.3	75.8
6	880	89	72.3
7	870	88.8	70.7
8	850	87.2	69.2
9	830	85.9	68.3
10	780	84.6	66.4

Source: Author.

Table 111.2. Descriptive statistics of minimum, maximum, mean, standard deviation, and standard error deviation of two groups with each sample size of accuracy BERT (74.45) and Roberta (89.21)

Algorithm Accuracy	N	Mean	Std. Deviation	Std. Error Mean
Roberta	10	89.22	2.99	0.947
BERT	10	73.54	4.72	1.493

Source: Author.

Table 111.3. Independent Sample T-Test results show the confidence interval as 95% and the P value is less than 0.05, (P<0.05) there is a statistical significance between these two algorithms

		Levene's test for equality of variances		T-test for equality means with 95% confidence interval						
		f	Sig.	t	df	Sig. (Single 2-tailed)	Mean difference	Std. Error difference	Lower	Upper
Accuracy	Equal variances assumed	5.896	0.026	8.866	18	.0.000	15.68	1.76	11.964	19.395
	Equal Variances not assumed			8.866	15.232	0.000	15.68	1.76	11.915	19.444

Source: Author.

4. Result

Accuracy of BERT algorithm question answering and data loss during text summarization are measured. For both model approaches, the overall Mean, Standard Deviation, and Standard Error mean are gathered throughout 15 iterations, as shown in Table 111.3.

Roberta Masked Text summarization data loss and question answering accuracy using the Language
Figure 111.1. Roberta algorithm Training, valuation accuracy of all sample epochs.
Source: Author.

Figure 111.2. BERT algorithm Training, valuation accuracy data of all sample epochs.
Source: Author.

Figure 111.3. Clustered Bar means the accuracy of Roberta is 95.1%. The x-axis of the bar is the two algorithms and the y-axis of the bar is the mean accuracy of ± 2SD. The performance of the Roberta algorithm is better than the BERT Algorithm.

Source: Author.

Modelling method are calculated. Figure 111.2 displays the overall mean, standard deviation, and standard error mean obtained over 15 iterations for both model approaches.

All sample epochs' valuation loss and training data for the Bert algorithm. Using accuracy % values and epochs, the algorithm's accuracy may be verified.

A comparison of the Novel Roberta and BERT algorithms is shown in Table 111.1 on N = 10 samples

of a dataset with the highest accuracy (95.1% and 79.1%) in the samples (when N = 1) using dataset size = 950 and 70% training and 30% testing data.

Table 111.2. Results of the Roberta and BERT approaches statistically. After 10 rounds, the Roberta and BERT algorithms determine the mean accuracy value, standard deviation, and standard error mean. The Roberta 95.11% algorithm performed better on average than the BERT 79.11% approach.

Table 111.3. The significance level of the Novel Roberta and BERT algorithms is insignificant in the independent sample t-test (p=0.117). As a result, with a 95.1% confidence interval, both the Novel Roberta and the BERT algorithms have a significance level smaller than 0.05.

The accuracy of the algorithm can be checked while training and loss of algorithm can be detected by subtracting the accuracy value with 100. The output of an independent sample test and significance of 0.001 (single-tailed), which is less than the level of significance 0.05. The corpus data summarized loss and the accuracy of the context summary shows that Roberta is faster than the BERT algorithm and takes the lesser parameters. Detailed evaluation is shown in tabular manner in Table 111.2 and in Figure 111.1 Novel Roberta algorithm training and valuation loss data for all sample epochs. The accuracy of algorithm can be checked using accuracy percentage values and epochs.

The two graphs are used to compare the loss and accuracy of Roberta and BERT. The accuracy of the Roberta algorithm is 95.1% and the accuracy of the BERT is ~79.1%. As can be seen in Figure 111.3, the Roberta algorithm performs better than the BERT algorithm.

5. Discussion

In the Innovation research study, Masked Language Modelling Algorithm Roberta has better significance in summarizing the faster and providing the 96% efficiency of the Roberta algorithm by using dynamic masked language modelling. Roberta's accuracy was calculated, and the results showed that the mean, standard deviation, and standard mean error were 95.1, 11.4, and 36.2, respectively. Since the training model was trained on 160 GB of data from Wikipedia and the Book Corpus, Roberta has outperformed Bert in several areas. Several tests like squad testing, glue testing have been performed. On intentionally creating diagnostic items that assessed the model's capacity for logical inference, BERT did badly. Roberta algorithm [7] has 74.6% accuracy, whereas Struct BERT algorithm [17] has 95.1% accuracy.

There are no discoveries that contradict this work. Roberta uses dynamic masked language modelling where pattern is generated every time a sequence is fed into the model. And the similar findings are [3, 4, 10, 12, 13, 23] and the opposed findings are [16]. It gives better results. For generating tokens, Roberta uses a byte pair encoding scheme with a vocabulary containing more than 60K units in contrast to BERT's character level BPE (Byte Pair Encoding) with 30K vocabulary.

Roberta's drawback is that it is susceptible to biased predictions, which can have an impact on even the model's refined versions. The model sometimes appears to react to the appropriate tokens, but it still doesn't respond. Roberta is often lagging behind other BERT implementations since it was designed to perform speedier on low-end devices. The goal of this research's future work is to speed up summarization while lowering the parameters used to create the unique method.

6. Conclusion

The Roberta method, in combination with innovative text summarization, may be utilized to summarize the text with an enhanced accuracy of 91.50% when compared to the BERT algorithm's 79.1% accuracy, according to the I research study. Roberta's mean accuracy error was likewise smaller than the BERT approach. Hence, the Roberta approach slightly outperforms the BERT algorithm in terms of accuracy.

112 Efficient prediction of man-in-middle-attack in IOT device using Novel Convolutional Neural Network compared with Google Net with improved accuracy

A. Kailashnath Reddy[a] and Mahaveerakannan R.

Department of Artificial Intelligence, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The purpose of this work is to improve the prediction of man in the middle attack in IOT devices. A Man-in-the-Middle attack occurs when a perpetrator eavesdrops or impersonates a user or program in a discussion. 10 sets of samples from each group are selected to anticipate the man-in-the-middle attack in Internet of Things devices. Novel Convolutional Neural Network and GoogleNet have correlation values with 96.76 % and 90.04 % respectively. Both algorithms were conducted with variable training and testing splits. Novel Convolutional Neural Network (93.9660%) outperforms ResNet50 (72.5420%) by 0.022 (two tailed, $p < 0.05$). Hence the P value is less than 0.05, (P<0.05) statistical significance exists between these two algorithms. Using g power setting values of 0.05 and 0.85, the test's average Gpower is roughly 85 %. Novel Convolutional Neural Network (93.9660%) has the increased accuracy over GoogleNet (84.598%) with a significance value of 0.001 (Two tailed, $p < 0.05$). The accuracy of Novel Convolutional Neural Network is better when compared to accuracy of GoogleNet.

Keywords: GoogleNet, man-in-middle attack, novel convolutional neural network, peaceful society, scan-based self anomaly detection, session hijacking

1. Introduction

The channel-based man-in-the-middle attack is by far the most dangerous of all of these vulnerabilities and attacks that may be launched against a system because it has the potential to compromise the widely used and secure Wi-Fi Protected Access 2 encryption and authentication protocol [13, 16]. When we update the IOT devices with more accurate predictions, the work and the development of the nations will be more gentle and peaceful. This study suggests an access point scan-based self anomaly detection security and prevention against channel-based man-in-the-middle attacks provided by the client side of the connection [13]. An attack known as a guy in the middle attack is comparable to a mailman reading your bank statement, jotting down your account data, resealing the envelope, and delivering it to your door. In the event that a client establishes a connection to an access point, it performs an access point scan to verify Extended Service Set ID and Basic Service Set ID uniqueness. Wireless devices are now capable, with the help of scanning-based irregularity detection carried out by the system on its own, of independently performing anomaly detection in order to verify the legality of wireless access points [15, 18]. Particularly advantageous for mobile clients like smartphones and Internet Of Things devices is Scan-based self anomaly detection capacity to operate in the presence of several wireless access points. Mostly the middle class people can be affected because of fraud links sent to them and development comes where the most people are there who have to live in a peaceful society. We evaluated the effectiveness of integrating scan-based self anomaly detection into a Wi-Fi network that is open-source and free to use client application [19]. The attacker passively intercepts network data to capture the target's session ID in passive session hijacking.

2. Materials and Methods

Research was conducted at the Saveetha Institute of Medical and Technological Sciences in the Soft Computing

Lab of the Department of Computer Science and Engineering in the Saveetha School of Engineering. The G power program carried out a comparison of the two controllers in order to ascertain the appropriate size of the sample to be collected. In order to evaluate both the process and the outcomes of the two groups, two groups will be selected. For the purpose of this investigation, ten samples were selected at random, ten being the number of sets taken from each group. Both the Novel CNN and the GoogleNet algorithms, which are both used for technical review, are both implemented with the help of specialist computer software. The Python OpenCV software was used throughout the planning and development process of the proposed work. Research on deep learning was carried out with the help of the Windows 10 operating system as the laboratory. This was the configuration of the hardware. The code will be implemented using Java, which was chosen as the language to use for the implementation of the code. This is being done while the code is being executed.

2.1. Novel convolutional neural network algorithm

Image recognition and other activities that call for the processing of pixel input are examples of the types of tasks that make use of Novel Convolutional Neural Networks as a specialized form of network architecture designed for use with deep learning algorithms [3]. Novel Convolutional Neural Networks are also known as convolutional neural networks. Convolutional neural networks have become widely used for a variety of computer vision applications, such as classifying pictures, identifying faces, detecting objects, etc.

2.2. Novel convolutional neural network algorithm

1. Import necessary modules: tensorflow, keras, datasets, layers, and models.
2. Load the MNIST dataset using the datasets module of Keras. The dataset consists of a total of 60,000 training shots and 10,000 test images, each of which has a resolution of 28 28 pixels.
3. Normalize the pixel values of the images to a range between 0 and 1 using the division operator.
4. Reshape the images to add a channel dimension, which is required for convolutional neural networks (CNNs). The input shape of each image is $(28, 28, 1)$ where 1 represents the channel (grayscale image).
5. Define a sequential model using the models module of Keras. Add layers to the model using the layers module of Keras. The layers are:
   a. Conv2D layer that contains 32 filter nodes and uses ReLU as the activation function. Kernel size is set at $(3, 3)$.
   b. It has been determined that a pool size of $(2, 2)$ should be used for the MaxPooling2D layer.
   c. Conv2D layer that contains 64 filter nodes and uses ReLU as the activation function. Kernel size is set at $(3, 3)$.
   d. It has been determined that a pool size of $(2, 2)$ should be used for the MaxPooling2D layer. e. Conv2D layer equipped with 64 filter nodes, a kernel size of $(3, 3)$, and ReLU activation function. f. In order to transform the 2D output of the previous layer into a 1D array, the layer must be flattened.
   g. a dense layer that consists of 64 neurons and has a ReLU activation function.
   h. There are ten different neural connections that make up the dense output layer.
6. Compile the model using the compile method of Keras. The loss function used is Sparse Categorical Crossentropy, which is suitable for multi-class classification problems with integer labels. The optimizer used is Adam, which is an adaptive learning rate optimization algorithm. The metric used to evaluate the model is accuracy.
7. Train the model by making use of the fit method that is contained within the Keras package. The information that was utilized for training, number of epochs, and validation data are passed as parameters.
8. Evaluate the model using the evaluation method of Keras. The test data and labels are passed as parameters. On the console, you will see an indication of the degree to which the model accurately represents the test data.

2.3. GoogleNet algorithm

The CNN GoogleNet (Iqbal et al., n.d.) developed by Google includes a total of 22 layers. Using either the ImageNet or the Places365] datasets, Loading a network that has been prepared to deal with the load is something that can be done. In ImageNet, there are thousands of categories that may be used to group images, like "keyboard," "mouse," "pencil," and "animal." The algorithm used to categorize images into 365 different site categories, such as meadow, parkland, airfield, and foyer, is quite similar to the one that was learned on ImageNet. Using a variety of feature representations, these networks have evolved to represent a wide range of visual data types.

Since there is a bias element for each filter, the total number of features in a Convolutional would be $((m * n * d)+1)* k$.

The same meaning can also be expressed as:

((the filter's width times its height times the number of screens in the input sequence plus one)*the number of filters)

Algorithm:

1. Import 1. Import the required libraries: The code starts by importing the necessary modules from the Keras API, such as the dataset module, model module, and various layers.
2. Load and prepare the data: The code then loads the MNIST dataset using the mnist.load_data() function from the Keras dataset module. It then reshapes the data into a 4D tensor format with dimensions (number of images, height, width, channels), where the channels dimension is set to 1 since the images are grayscale. The pixel values are also normalized to be in the range [0, 1].
3. Defining the model architecture: The code defines a Sequential model object and adds the layers in sequence. To begin, a convolutional layer is added with 32 filters of size 3x3 and a ReLU's role in the activation function. The size of each filter in this layer is 3x3. After this comes a maximum pooling layer that has a pool size of 2x2 pixels. After that, the output is flattened before it is passed through a fully connected layer that has a hundred neurons and an activation function that uses the ReLU algorithm. In the end, a prediction of the class probabilities for each digit is created by inserting an output layer that is comprised of 10 neurons and a softmax activation function. This layer is included in the neural network.
4. Compile the model: During the process of compilation, the model is provided with the sparse_categorical_crossentropy loss function, the adam optimizer, and accuracy is selected to act as the evaluation measure. All of these components are given to the model.
5. Train the model: The model is trained for 10 epochs using the fit() function on the training set.

2.4. *Statistical analysis*

In order to do statistical analysis on Novel Convolutional Neural Network and GoogleNet [8], the program known as SPSS is utilized. Independent variables are images, objects Dependent variable is accuracy, Mean, Standard Deviation. Independent T test [14]. The two approaches are put through analysis in order to calculate their respective degrees of accuracy.

3. Results

Both of these are viable options Novel CNN and GoogleNet were run in Anaconda Navigator at a number of different moments in time, with the sample size being set at ten individuals. Both of these programmes were used to analyze the data. Table 112.1 demonstrates the expected accuracy and loss of the Novel Convolutional Neural Network. Table 112.1 also includes an illustration of the expected loss and accuracy of GoogleNet.

Table 112.2 shows In order to generate statistical values that may be compared with one another, these ten data samples are used for each method, together with the values that correspond to the losses experienced. After that, a discussion regarding these outcomes is possible. According to what was discovered in the research, Novel CNN mean accuracy was 93.9660 % while GoogleNet's was 61.9510 %. For Novel Convolutional Neural Network and GoogleNet, The following table presents the mean values for the degree of accuracy in Table 112.2. With a standard deviation of 2.21290 compared to GoogleNet's 4.43445, Novel CNN mean value is superior. The findings from Novel Convolutional Neural Network and GoogleNet's A display of independent sample T tests is available for perusal in Table 112.4 at a level of statistical significance of 0.058 (two-tailed test, significance level of

Table 112.1. Accuracy and of novel convolutional neural network

Iterations	Accuracy Novel CNN k (%)	Accuracy Googlenet (%)
1	94.33	78.99
2	96.47	80.65
3	93.93	81.78
4	90.70	82.11
5	94.54	85.00

Figure 112.1. The news network in question A comparison is made between the novel convolutional neural network and the search engine GoogleNet. Classifier in regard to the amount of loss and the overall accuracy. The level of precision that the Novel Convolutional Neural Network typically achieves in its calculations beats that of GoogleNet. When it comes to classification, the standard deviation produced by Novel CNN is a little bit superior to that produced by GoogleNet. On the X axis, we have the Novel Convolutional Neural Network vs the GoogleNet Classifier, and on the Y axis, we have the mean detection accuracy with +/-2SD.

Source: Author.

p 0.05). The results, expressed in terms of the mean accuracy and loss, are shown in Figure 112.1 compares Novel CNN with GoogleNet.

Table 112.3 demonstrates that the mean, standard deviation, and standard error mean for each variable are as follows: Novel CNN are 93.9660, 2.21290, and 0.69978 respectively. These figures were derived from the collected data. In addition, the mean value for GoogleNet is 61.9510, while its standard deviation is 4.43445 and its standard error mean is 1.40230. With a p value of 0.001, the difference between CNN and GoogleNet is so small that it cannot be considered statistically significant (two-tailed, p less than 0.05).

Table 112.4 The values of the group statistics are displayed, and additional information such as the mean, standard deviation, and standard error mean for each of the two approaches is also given in this presentation. Additionally, the values for the group statistics are shown in the table. The methods of loss that are used by Novel CNN and the two algorithms that are utilized by GoogleNet are contrasted and visually displayed. This shows that the Novel CNN contains a classification accuracy that is 93.9660%, which is much greater than the accuracy that is acquired by GoogleNet, which is 61.9510%. Specifically, the accuracy that is obtained by the Novel CNN is 93.9660%.

Figure 112.1 shows the news network Comparing Novel Convolutional Neural Network to GoogleNet. Loss-based classifier. Novel Convolutional Neural Network's average accuracy beats GoogleNet. Novel Convolutional Neural Network's classification standard deviation is somewhat better than GoogleNet's. Newal Convolutional Neural Network vs. GoogleNet

Classifier on X and mean detection accuracy with +/-2SD on Y.

4. Discussion

According to the findings of the aforementioned research, the significance value was found to be 0. When compared to the accuracy of the Novel Convolutional Neural Network, which is analyzed as having a value of 93. 9660%, the accuracy of the Novel Convolutional Neural Network is judged to have a value of 61. This is in comparison to the accuracy of the Novel Convolutional Neural Network. In the context of implementations of sensor cloud systems for the Internet of Things, dependable device-to-device direct communication is one of the most important aspects of the study. It's probable that the mechanism for access control will ensure the reliability of the system of any two Internet of Things devices through encrypted, mutually-trusted communication. The generation of a shared session key and mutual authentication are the two main components of the two-pronged strategy that is required. Scan-based self anomaly detection creates a barrier that prevents channel-based man-in-the-middle attacks from being successful. It is designed to work with various devices that are connected to the Internet of Things. This research has certain disadvantages, the most significant distinction is the fact that training a Novel Convolutional Neural Network takes an extremely long amount of time yet, in the end, produces more precise numerical outputs.

5. Conclusion

In comparison, According to the results of our calculations, Novel CNN possesses an accuracy value of 93.9660%, while the accuracy value of GoogleNet is 61.9510%. According to the research, GoogleNet (61.9510%) performs worse than Novel CNN (93.9660%). So the CNN has the most accurate value then Google Net cause it is 22 layers deep down to the Novel CNN.

113 Accuracy of comparing the effectiveness of AlexNet and support vector machine in predicting PCOD in women

B. Hasritha[a] and R. Gnanajeyaraman

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The primary objective of this research is to improve accuracy of forecasting PCOD difficulties in women based on the online PCOD DB dataset utilizing two Deep Learning (DL) methodologies, namely SVM and AlexNet classifiers. AlexNet and SVM classifiers are employed to detect PCOD problem using the models that have been designed. The experimental phase uses the PCOD DB dataset, and the system's creation is accomplished using the python programming software. Group 1 is taken as AlexNet and group 2 as Novel Support Vector Machine was calculated as a total of 15 sample sizes. By using the GPower 3.1 software (g power setting parameters: alpha = 0.05 and G power = 0.8). The recommended AlexNet classifier accuracy level is confirmed with 92.99%. AlexNet and SVM classifier's processing time is also calculated. Based on obtained results Alexnet has significantly better accuracy with 92.99% compared to SVMs accuracy (90.87%). Statistical significance difference between Alexnet and SVM algorithm was found to be Independent samples T-test found to p=0.001 (p<0.05) it is evident that there is an existence of statistically significant differences between these two groups. The recommended research process, the finalized result indicates that the AlexNet model's performance is superior to the SVM classifier when it comes to predicting PCOD from the online dataset PCOD DB.

1. Introduction

The healthcare business is now highly reliant on Machine Learning, a field of study that allows machines to learn without even being stated in the previous. A medical illness such as PCOS lacks a definitive diagnosis and treatment options [12]. It's a common hormonal disorder that leads ovarian cysts to grow in child-bearing females, leading to infertile. The main reason for this research is to predict the PCOD problem in women and how they overcome the disease. Over the last five years, Science Direct has published more than 150 research papers covering a wide range of machine learning concepts. PCOD, Women with PCOD have 10–12 cysts in the ovary, even though more than 10 tumors are needed to identify the illness based on ultrasound pictures. Because the chance of acquiring PCOD is increasing, current research employs cutting-edge IT approaches such as

Machine Learning algorithms, which can be used to anticipate PCOD based on a person's present health and so assist them in recognizing [5, 13] the likelihood of PCOD. By utilizing machine learning algorithms, tailored treatment plans for women with PCOD can be formulated based on their distinct attributes such as hormonal profiles, lifestyle factors, and genetic information. With the aid of data analysis and integration, these machine learning algorithms have the potential to enhance treatment plans and cater to the individual needs of each woman with PCOD, thereby increasing the efficacy and personalization of management strategies. Ultimately, the aim is to reduce the prevalence of PCOD among affected women.

2. Materials and Methods

The Deep Learning and Machine Learning Laboratory at Saveetha School of Engineering, SIMATS (Saveetha

[a]susansmartgenresearch@gmail.com

Institute of Medical and Technical Sciences) conducted and carried out the development of this research task. The Group 1 being identified as AlexNet and group 2 as an SVM classifier was calculated as of 15 sample sizes. Using the GPower 3.1 programme (with g power values between 0.05 and 0.8) [14].

After obtaining the PCOD DB dataset from an online resource, repetitive and undesirable dataset parts were removed using data pre-processing techniques. Afterwards, in relation to the relevant data sets, the accuracy rates of the AlexNet and SVM classifiers are assessed and contrasted. In this research, web-based material is collected and applied experimentally. Systems for predicting PCOD sickness are developed using Python programming. Python software is one of the well-known software tools for developing Deep Learning models and analysing the outcomes. It includes a variety of tools and built-in library functions that are used for the whole range of Deep Learning classifier-related tasks. The PCOD DB dataset has been selected as the dataset for both training and testing purposes. It consists of 400 records, with 80% of them utilized for training and the remaining 20% allocated for testing [14].

The proposed algorithm is the Alexnet which is called as group 1 and it is the highest classification efficiency and is composed of eight layers, three of which are fully connected and five of which are convolutional uses Relu is AlexNet. The Compared algorithm as the Support Vector Machine which is called as group 2 and the SVM model is data-driven and model-free, and as a result, it may have a large amount of discriminative power for classification, especially in situations with a small number of parameters.

2.1. AlexNet

AlexNet demonstrated high classification effectiveness, but the training required was lengthy. The structure is made up of eight-level layers, five of which are convolutional and three of which are fully linked in machine learning. AlexNet uses Relu rather than the usual tan h method. The accuracy level of the Alexnet is 92.99%.

AlexNet supports multi-GPU training by distributing half of the model's neurons to one GPU and the other half to another. AlexNet contained 60 million variables, which was a significant issue in the sense of overfitting. To minimize overfitting, data augmentation and dropout approaches were used. AlexNet is a remarkably strong model that can achieve high levels of accuracy on extremely difficult datasets. AlexNet is a leading design for any kind of object-detection job, and it has potentially enormous uses in the Machine Learning sector of AI-related issues.

2.2. Pseudocode for AlexNet

Load the source picture and normalize it appropriately before processing it (e.g., subtracting the mean pixel values).

Apply the first convolutional layer, which consists of 96 filters with a size of 11x11, a stride of 4, and a padding of 0.

Use the activation function for the Rectified Linear Unit (ReLU).

Across channels, use Local Response Normalization (LRN).

Apply maximum pooling using a 3x3 filter size and a 2 stride.

Apply the second convolutional layer, which has 256 filters of size 5x5 with a stride and padding of 1 and 2, respectively.

Activate the ReLU with this function.

Use LRN across all channels.

Apply maximum pooling using a 3x3 filter size and a 2 stride.

2.3. Support vector machine (SVM)

After computationally transforming the inputs into a high-dimensional space, Support Vector Machine segregates between 2 categories by constructing a hyperplane that completed various classes. The Support Vector Machine model may provide great discriminative potential for categorization as it is data-driven and model-free, especially in scenarios with a small and large number of factors. This technology has recently been applied to generate computerized disease categorization and to enhance strategies for disease detection in the healthcare setting.

SVM works by transferring the data to a high-dimensional feature set to categories data points that are otherwise not differentiable. A splitter between both groups is discovered, and the data are processed so that the divider may be represented as a hyperplane. Following that, fresh data features can be utilized to determine the category that a new record may belongs.

2.4. Pseudocode for SVM inputs: determine the various training and test data

Outputs: Determine the calculated accuracy.

Select the optimal value of cost and gamma for SVM.

While (stopping condition is not met) do

Implement SVM train step for each data point.

Implement SVM classify for testing data points.

End while Return

Accuracy

2.5. Statistical analysis

To determine the value of SD (Standard Deviation), mean deviation data, significance point data, and also to create graphical representations, etc., statistical software tool IBM SPSS with the well-known version 26.0 ("Downloading IBM SPSS Statistics 26" 2022) is used. In the current research method, the SPSS programme was chosen to examine the relevant PCOD DB dataset.

Independent variables include the image, objects, distance, modulation, amplitude, beta, and others. Images, periods, weights, heights, and objects are dependent variables. An independent T test analysis is conducted for both processes to ascertain accuracy.

4. Results

The PCOD DB dataset is examined using the MATLAB software tool, and the SVM RF and AlexNet classifiers' accuracy rates are compared. The suggested AlexNet gives a higher accuracy rate than the Support Vector Machine and RF for the provided datasets.

The accuracy values of AlexNet and Support Vector Machine AlgorithmRandom Forest are shown in Table 113.1. The accuracy mean value for Alexnet and Logistic Regression is 92.99% and 90.8754%, respectively, according to Table 113.2, which shows group statistics based on the online PCOD DB dataset of the suggested study effort and the Standard Deviation of Alexnet is 1.234 and the Standard Deviation is 1.769.

The accuracy value of the AlexNet, Support Vector Machine, Random Forest, and Independent Samples Test is shown in Table 113.3. Processing time for Random Forest and Support Vector Machine is also calculated. In Alexnet and X-Gradient algorithms' statistical differences with Random Forest.

Figure 113.1 shows a graphic comparison of the mean accuracy between Alexnet and Support Vector Machine. The Alexnet algorithm significantly increases accuracy in the PCOD problem compared to the Support Vector Machine algorithm. Y Axis: Mean accuracy of detection with +/- 2SE and X Axis: Alexnet Algorithm vs Support Vector Machine.

5. Discussion

The SVM classifier is utilized in the earlier research work; the accuracy rate is 90.87% on average. There is a programme called AlexNet, with a mean accuracy rating of 92.99%. The Independent Samples T-test revealed a statistically significant value difference between Alexnet and Support Vector Machine of p=0.001 (p<0.05) which is statistically significant. For considerable accuracy in the PCOS dataset, AlexNet surpasses X-Gradient Boosting classifier techniques.

Introduced an automatic Deep Learning approach for auxiliary PCOD diagnosis, which investigates the possibility of scleral alterations in PCOD identification [10]. This technique produces an average AUC of 0.979 and an accuracy rate of 0.929, indicating the great promise of Deep Learning in the identification of PCOS [9]. Furthermore, the PSO-based approach avoids the issue of attribute subset repetition. This results in infertility and a variety of illnesses in women. This condition's major signs are abnormal menstruation, oiliness, acne, high blood pressure, and anxiety issues [11]. They tested this framework on a Kaggle dataset to validate the efficacy of these proposed observations, and the Extreme Gradient Boosting classifier exceeded all other classification models with only

a 10 Fold Cross-validation rating of 96.03% overall, as well as a 98% Recall in the identification of patient populations without PCOD [1].

PCOD is a chronic illness for which there is no known treatment. There is no known cure, but there are treatment alternatives to manage the symptoms and potential health hazards. The disorder may therefore need to be managed by PCOD sufferers both during and after their reproductive years. The Future Scope is to raise awareness and educate people about PCOD, including patients, healthcare professionals, and the general public. This could result in an earlier diagnosis, better treatment, and an overall higher quality of life for women with PCOD. Future initiatives might concentrate on increasing awareness, lowering stigma, and promoting legislative reforms to enhance PCOD care and assistance [12].

6. Conclusion

Compared to SVM classifiers, AlexNet, which is recommended, produces superior results with an accuracy rate of 92.99%. The execution time is also significantly faster, taking only 0.5 seconds. The Independent Samples T-test reveals that there is a statistically significant difference (p=0.001, p<0.05) between the Novel AlexNet and Support Vector Machine-Random Forest. The accuracy rate of AlexNet is 92.99%, while the accuracy rate of Random Forest is 90.54%. Based on accuracy and significance AlexNet performed better than Support Vector Machine with the PCOD dataset.

114 Prediction of accuracy for highest bid of products in online auction system using support vector machine in comparison with K-means clustering

M. Gowri Charan[a] and K. Anbazhagan

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The main goal of this study is to compare and contrast the K-Means Clustering Algorithm and the SVM algorithm for online auction price prediction systems in order to increase the accuracy of the price forecast. The parameters for the SVM Algorithm (N=10) and K-Means Clustering (N=10) are minimised by simulation. 20 samples are studied in this study, and the sample size for two groups is determined using the Gpower 80 percent formula. Linear Regression achieves 93.6% accuracy in predicting the price of an item in an online auction, the proposed system, which uses SVMs, achieves 97.2% accuracy in classifying whether an item will be sold or not. The significance level of the research was determined to be P=0.001 (p<0.05) and a confidence interval level of 95%. In terms of accuracy, the SVM algorithm (97.2%) outperforms the K-Means Clustering Algorithm (93.6%).

Keywords: Novel support vector machine, novel K-means clustering, machine learning, price forecasting, trade, real time bidding analysis, price trend analysis

1. Introduction

This auction will be facilitated through the use of online software that can regulate the processes involved. There are many different auction methods and types and one of the most popular is the English Auction System [18]. The online auction system has several names such as e-auction, electronic auction. Online bidding is prevalent in all kinds of industrial applications. It includes not only the products and goods you sell, but also the services you can provide. There have been 257 publications published on IEEE, and there have been 1340 online articles and journals published overall based on the Online Price Prediction method in Google Scholar. The system is highly scalable and designed to support large numbers of bidders in active auctions [21, 22]. User data may be kept confidential for the validity and integrity of the contractual documents. Due to the popularity of online auctions in recent years, there has been more empirical research on the topic [1, 23]. This information aids us in developing the numerous apps and services that we may provide to users of our online marketplace, including both buyers and sellers. It gathers information from online auctions for trade and uses a variety of categorization algorithms to forecast predicted selling values for products. eBay is one of the key factors influencing this desire. eBay sells 4,444 million products daily in countless categories. The majority of these studies consider data from online auctions as cross-cutting data and neglect the shifting dynamics that take place during the auction. The research gap in the existing system is to predict the highest price for online auction accuracy is less and to develop more accurate and efficient prediction models that incorporate external factors and account for the dynamic and complex nature of online auctions.

2. Materials and Methods

The project is divided into two groups: the SVM is the first group, and the K-Means clustering is the second.

The sample size was calculated using the Sample Size Calculator (clincalc.com) with a level of 0.07 and a G capacity of 35%, and a certainty range of 95.0% and the dataset for this project is taken from kaggle [8]. The dataset for this particular research topic was retrieved from the Kaggle repository 25% of the database is set aside for testing, while 75% is reserved for training. For testing, a Java programming environment named Netbeans is employed. SPSS version 26.0.1 and a laptop with an i5 CPU from the 10th generation, 8GB of RAM, and a 4GB graphics card.

2.1. *Support vector machine algorithm*

The computational cost of the SVM method does not depend on the dimensionality of the input space, and its sophisticated learning model fits the model's capacity to the complexity of the input data, assuring extremely strong performances on future data that has not yet been observed. Because of their more general nature, support vector learning algorithms have a very wide range of applications, and all feed-forward NNs may employ them in their learning process.

2.1.1. *Algorithm*

Step 1: Collect the data for the online auction, including features such as the product description, starting bid, bidding history, and bidder information.

Step 2: Preprocess the data by removing any irrelevant features and cleaning the data (e.g., removing missing values, outliers, and duplicates).

Step 3: Split the data into a training set and a testing set.

Step 4: Scale the features to ensure that they are all on a similar scale.

Step 5: Train the SVM model on the training set using an appropriate kernel function (e.g., linear, polynomial, or radial basis function).

Step 6: Evaluate the performance of the model on the testing set using metrics such as accuracy, precision, recall, and F1-score.

Step 7: If the performance of the model is not satisfactory, tune the hyperparameters of the SVM (e.g., regularization parameter, kernel coefficient) using a cross-validation approach.

Step 8: Once the model is satisfactory, use it to predict the outcome of new online auctions by feeding in the relevant features of the auction.

Step 9: Monitor the performance of the model over time and retrain it periodically to ensure that it remains accurate and up-to-date.

2.2. *K-means clustering*

Unsupervised learning algorithm K-Means Clustering divides the unlabeled dataset into several clusters.

Here, K specifies how many predetermined clusters must be established as part of the process; for example, if K=2, there will be two clusters, if K=3, there will be three clusters, and so on. It is an iterative approach that separates the unlabeled dataset into k distinct clusters, each of which contains just one dataset and shares a set of characteristics. It gives us the ability to divide the data into several groups and provides a practical method for automatically identifying the groups in the unlabeled dataset without the need for any training.

Each cluster has a centroid assigned to it since the technique is centroid-based. This algorithm's primary goal is to reduce the total distances between each data point and each of its related clusters. The method starts with an unlabeled dataset as its input, separates it into k clusters, and then continues the procedure until it runs out of clusters to use. In this algorithm, the value of k should be preset.

2.2.1. *Algorithm*

Step 1: Collect data: Gather data on previous online auctions, including information on the items sold, the starting prices, the number of bids, and the final prices.

Step 2: Normalize data: Normalize the data by scaling the features to have a mean of 0 and a standard deviation of 1. This is important because the k-nearest neighbor algorithm is distance-based, and features with large ranges can dominate the distance calculation.

Step 3: Split the data: Split the data into a training set and a test set. The training set will be used to fit the k-nearest neighbor model, while the test set will be used to evaluate the model's performance.

Step 4: Select k: Choose a value for k, which is the number of nearest neighbors to consider when making a prediction. This value should be chosen through trial and error or cross-validation.

Step 5: Predict: For each item in the test set, calculate the distance to each item in the training set using a distance metric such as Euclidean distance. Then, select the k nearest neighbors based on their distances.

Step 6: Decide prediction: Based on the k nearest neighbors, predict the final price of the item using regression or classification. For regression, take the average of the final prices of the k-nearest neighbors. For classification, take the mode of the classes of the k nearest neighbors.

Step 7: Evaluate: Evaluate the performance of the model by comparing the predicted final prices to the actual final prices in the test set using a performance metric such as mean squared error or accuracy.

Step 8: Optimize: Optimize the model by adjusting the value of k or by using feature selection or engineering techniques to improve the performance of the model.

Step 9: Deploy: Once the model has been optimized, deploy it in a production environment to make online auction price predictions.

2.3. *Statistical analysis*

The output is created with Python software [11]. Training these datasets requires a display with a resolution of 1024x768 pixels (10th generation, i5, 12GB RAM, 500 GB HDD). In order to do a statistical analysis of the ANN and HMM algorithms, we employ SPSS [24]. Means, standard deviations, and standard errors of means were computed by using SPSS to run an independent sample t test and then compare the two samples. Price dollar, proxy, reserve price, and increments are dependent variables. Time delay, combat sniping, pricing, and payment delay are all independent variables.

3. Tables and Figures

Table 114.1. The statistical calculations for the SVM and KMC classifiers, including mean, standard deviation, and mean standard error. The accuracy level parameter is utilised in the t-test. The Proposed method has a mean accuracy of 97.25 percent, whereas the KMC classification algorithm has a mean accuracy of 93.63 percent SVM has a Standard Deviation of 0.21029, and the KMC algorithm has a value of 2.54674. The mean of SVM Standard Error is 0.10291, while the KMC method is 0.87862

Group		N	Mean	Standard Deviation	Standard Error Mean
Accuracy rate	KMC	10	93.63	2.54674	0.87862
	SVM	10	97.25	0.21029	0.10291

Source: Author.

Table 114.2. The statistical calculation for independent variables of SVM in comparison with the KMC classifier has been evaluated. The significance level for the rate of accuracy is 0.029. Using a 95% confidence interval and a significance threshold of 0.79117, the SVM and KMC algorithms are compared using the independent samples T-test. This test of independent samples includes significance as 0.001, significance (two-tailed), mean difference, standard error difference, and lower and upper interval difference

Group		Levene's Test for Equality of Variances		T-Test for Equality of Means					95% Confidence Interval	
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	(Lower)	(Upper)
Accuracy	Equal variances assumed	1.234	0.029	12.263	38	.001	9.70250	0.79117	8.10086	11.30414
	Equal variances not assumed			12.263	37.520	.001	9.70250	0.79117	8.10086	11.30481

Source: Author.

4. Results

Figure 114.1 compares the SVM accuracy to that of the K-Means Clustering classifier. The SVM prediction model has a greater accuracy rate than the K-Means Clustering classification model, which has a rate of 93.63 (Data mining driven agents) [19]. The SVM classifier differs considerably from the Linear Regression (test of independent samples, p 0.05). The SVM and K-Means Clustering precision rates are shown along the X-axis. Y-axis: Mean keyword identification accuracy, 1 SD, with a 95 percent confidence interval.

In Table 114.1 The SVM and K-Means Clustering statistical computations, including mean, standard deviation, and mean standard error, are shown. The t-test uses the accuracy level parameter. The K-Means Clustering algorithm's mean accuracy is 93.63 percent, compared to the Suggested method's mean accuracy of 97.25 percent. The K-Means Clustering technique has a value of 2.54674, whereas the SVM has a Standard Deviation of 0.21029. The K-Means Clustering approach has a mean SVM Standard Error of 0.87862 whereas the SVM Standard Error is 0.10291.

In Table 114.2 The statistical results for SVM's independent variables in comparison to K-Means Clustering are shown. The accuracy rate has a significance level of 0.029. The independent samples T-test is used to compare the SVM and K-Means Clustering methods
Figure 114.1. Comparing the accuracy of the SVM classifier to that of the KMC algorithm has been evaluated. The Bayes prediction model has a greater accuracy rate than the LR classification model, which has a rate of 93.63. The SVM classifier differs considerably from the K-Means Clustering (test of independent samples, p 0.05). The SVM and LR precision rates are shown along the X-axis. Y-axis: Mean keyword identification accuracy, 1 SD, with a 95 percent confidence interval.

Source: Author.

with a 95% confidence interval and a significance level of 0.79117. This test of independent samples contains lower and upper interval difference, mean difference, standard error difference, significance (two-tailed), significance (0.001), and significance (two-tailed).

5. Discussion

In the current investigation, we found that (p=0.001, Stratified Random Analyst) the deep learning, machine learning SVM algorithm appears to have a greater success rate than the K-means clustering. This SVM's improved precision is greater than the K-means clustering algorithm (mean precision = 93.6390) and while using independent sample T-tests.

The percentage of accurately [20] detected affirmative tuples is the sensitivity. To determine whether a product would sell or not, the current approach employed SVM. The current system solely employed item title text as a feature vector when using SVM [14]. The accuracy of the current method is greater than 75% [3, 5, 16, 17]. SVM was employed in the suggested system, which performs better than the current system. Compares the proposed system, which employed SVM for item categorization, to the existing system.

The lack of data is one of the main limitations for online auction prediction systems. The system needs a large amount of historical data to be trained and tested [15]. The system's predictions might be off if the data is unreliable, erroneous, or prejudiced. To produce forecasts, online auction prediction systems require sophisticated algorithms and models. The Future is that the use of online auctions with blockchain technology can

benefit from increased user confidence and transparency. It is conceivable to develop a more secure online auction by combining blockchain technology with prediction systems.

6. Conclusion

One will infer from the experiment that it is successful and extremely beneficial compared to the K-Means Clustering approach, SVM is able to achieve a high identification rate and accuracy. An analysis of Online Auction Predicting System with an improved accuracy rate reveals that the SVM has an accuracy rating that is 97.25% more accurate than the K-Means Clustering, which has an accuracy rating that is only 93.63% accurate. This indicates that Support Vector Machine is superior to K-Means Clustering by 97.25%.

115 Forecasting sales for big mart using NovelXGBoost algorithm in comparison of accuracy with linear regression

Akshay Kumar Raju P.[a] and Parthiban S.

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The purpose of this analysis is to perform statistical analysis to evaluate the sale in bigmart using previous year sale data by different machine learning (ML) classifiers. For this research, NovelXGBoost and linear regression are chosen. Materials and Methods: Choosing a data collection, training it, and testing it with proposed classifiers are all part of this process. In order to train the suggested ML classifier model, 80% of the dataset volume is used, while the left over 20% is used for testing. Intended for the purposes of SPSS analysis, the outcomes of two classifiers are divided into two groups, each of which consists of 10 outcome values from various functional activities, for a total of 20. The values for the SPSS analysis's CI and alpha parameters are 0.292 and 0.95, respectively. Result: Using a Python compiler, the experimental analysis is performed, and the accuracy gains of the two classifiers are contrasted. The chosen Novels XGboost classifier enhanced bigmart sales prediction with an overall accuracy of 93.81%, and the LR classifier improved accuracy by 87.30%. Two groups were found to be statistically significant, with a p value of 0.001 (p < 0.05). Conclusion: The presentation of machine learning techniques could offer a useful approach for shaping data and making decisions. There will be an implementation of new strategies which can effectively pinpoint consumer requirements and develop marketing strategies. The output of machine learning algorithms will assist in choosing the best algorithm for predicting demand, that Big Mart uses to plan its marketing activities.

Keywords: Bigmart, sale, machine learning (ML), NovelXGBoost classifier, linear regression, profitability

1. Introduction

The struggle between competing businesses is getting more intense daily as a result of the quick expansion of international mall and store chains and the rise in customers using electronic payments [13]. Any business is working to increase its customer base by employing individualized and limited-time offers, therefore being able to anticipate future sales volume of each product is crucial for planning and inventory management in every business, transportation service, etc. [1, 12]. Sophisticated machine learning techniques can now be used for this owing to the inexpensive availability of computation and storage [1]. The applications are spam detection [14], wine quality prediction and hand gesture recognition [17].

From the year of 2005 to 2023, a grand total of 2300 articles were reviewed and the articles chosen from IEEE Xplore counts 850, 270 from Researchgate, 1030 from Elsiver and 150 from Springer. A statistical method of sale prediction on amazon done by [20] using AMIRA to predict quarterly sales. Between the years 2000 to 2103, the sale details of amazon are used as a dataset for this analysis and errors are measured through the root mean squared error method. During the Chinese festival, the users' browser searching behavior of specific items and purchasing behavior based on online sale prediction done by [16, 21] recommended collaborative filtering [19] used a regression model and neural network to enhance the sale ratio and target customer's behavior [8]. Done market segmentation and it depends on the customer's zone. For this analysis, K-means clustering is recommended and the categorization based on age and purchase of products on black Friday [9, 10]. Introduced Apriori association rule learning to analyse customer's interest

in purchasing products which led to a new marketing strategy needed in future to maximize the sale. The use of statistical data from previous year's sales, monthly sales, and the stocks in hold (ML) is a potential strategy for machine learning to more accurately identify sales on Bigmart. Traditional methods used smaller datasets to detect and evaluate the quality. This study was able to more precisely pinpoint the sales on a bigmart by using the complete data.

2. Materials and Methods

This investigation work was done by the Department of Computer Science Engineering at the Saveetha School of Engineering, an affiliate of the Saveetha Institute of Medical and Technical Sciences. The NovelXGBOOST and LINEAR REGRESSION classifiers were used in this investigation, as well as 20 samples. The Python compiler is used for bigmart sale prediction for a short duration or long term as per the availability of stock and daily sale. The statistical analysis for our study was carried out using IBM SPSS software version 26 [6,18].

The Big Mart sales dataset, obtained from Dataworld.com [3] contains information on daily sales, product details, and branch-wise sales. The dataset includes 12 variables, with a total of 20 samples, with ten samples allocated to each of the two groups. The data was separated into training and testing sets, with ten samples in each set. Peng and Wang (2019) used Clinccalc.com to determine the sample size, which resulted in a G-power of 0.8, alpha and beta values of 0.05 and 0.2, respectively, and a 95% confidence interval. The study's objective was to assess the accuracy of two models, NovelXGBoost and Logistic Regression, which were both trained on training data and tested on a test set to determine their accuracy.

2.1. NovelXGBoost classifier

NovelXGBoost is a dependable and scalable ensemble strategy for solving machine learning problems based on gradient boosting. Similar to gradient boosting, it builds an additive extension of the objective function by minimizing a loss function. However, NovelXGBoost uses a distinct loss function to regulate the complexity of the trees, as it only uses decision trees as its fundamental classifiers. In NovelXGBoost, distinct trees are constructed by numerous cores in XGBoost, and data is structured to reduce search time. This reduces the time required to train models, leading to better performance.

2.1.1. Pseudocode for NovelXGBoost algorithm

Step 1: The selected data is loaded to the system.
  Step 2: The modification of dataset has to be done.

Step 3: Attributes are chosen and features needed for improvising the classification are extracted. Step 4: Train the model with selected features.
  Step 5: Complete classification.

2.2. Linear regression (LR)

A statistical method for determining the value of a dependent variable from an independent variable is linear regression [4]. A measure of the connection between two variables is linear regression. A dependent variable is foreseen using this modeling approach depending on one or more independent factors. Among all statistical methods, the linear regression method is the one that is most frequently utilized.

2.2.1. Pseudocode for linear regression

Step 1: Collecting required volume of dataset.
  Step 2: Next stage is pre-processing.
  Step 3: If any noise or empty spaces are there, it needs to be removed for further processing.
  Step 4: The model for the classification process is developed and trained.
  Step 5: The classification is done with required accuracy range.

3. Statistical Analysis

Using a large dataset, the analysis and identification of sales at big marts were performed to enhance sales across different durations such as daily, weekly, monthly, and yearly. The Python compiler was used to obtain accuracy values using essential features. IBM SPSS version-26 software was utilized for statistical analysis of the output obtained from the Python

Table 115.1. Accuracy comparison of Conventional and Proposed method the XGBoost has occurred with 98.76%and HEI has occurred 94.95% and the XGBoost has more accuracy than the HEI

Accuracy (%)

compiler. The dataset collected for this study includes details of annual sales, peak hour sales, and other essential attributes chosen as independent variables, with the goal of achieving higher accuracy gains, which are considered dependent variables [5].

4. Result

Two separate classifiers, XGboost and LR classifier, are used to analyse and identify big-mart sales using a vast amount of dataset and improve the sale on various time scales, including a single day, weekly sale, monthly sale, and yearly sale. The accuracy gains of the XGboost and LR classifiers were measured as 93.81% and 87.30% by the Python compiler. The suggested XGboost classifier can predict sales in bigmarts, malls, and small stores at a tremendous pace with accuracy that exceeds that of similar classifiers.

Table 115.1 having the accuracy gain of XGboost and LR classifier obtained from python compiler at 10 different instants.

Data from Table 115.1 were used as input for the SPSS statistical analysis, which conducted a comparative mean test. The group statistical analysis and independent sample tests are subcategories of the comparative mean test. When group statistics initially run, data are rejected in Table 115.2. The mean accuracy, standard deviation, and standard error mean are estimated using 10 samples per group. Group 1 values are 93.6960%, 3.34142, and 1.05665, whereas group 2 values are 87.8230%, 2.98841, and 0.94502 respectively.

Table 115.3 makes the assumption and the non-assumption that the accuracy of the classifiers under consideration varies equally. The value of p is held constant at p<0.05 throughout this analysis.

The visualization created by a statistical study is shown in Figure 115.1. A comparison graph of the mean accuracy for recommended and standard classifiers was made using the mean accuracy value that was chosen from Table 115.2. The recommended classifiers are shown on the X-axis, while the accuracy value is

Table 115.2. The mean and standard deviation of the group and accuracy of the XGBoost and HMM algorithms were 95.4540% and 2.43310, 91.3620% and 3.04141, respectively. In comparison to the LR, XGBoost had a lower standard error of 0.77257

	GROUP NAME	N	Mean	Standard Deviation	Standard Error Mean
			Group Statistics		
Accuracy	XGBoost	10	93.6960	3.34142	1.05665

		Levene's Test for Equality of Variances		T-test for Equality of Means					95% Confidence Interval of the Difference	
		F	*Sig.*	*T*	*Df*	*Sig. (2-tailed)*	*Mean Difference*	*Std. Error Differences*	*Lower*	*Upper*
Accuracy	Equal Variances assumed	.177	.679	4.143	18	.001	5.87300	1.41759	2.89475	8.85125
	Equal Variances not assumed			4.143	17.780	.001	5.87300	1.41759	2.89211	8.85389

Source: Author.

shown on the Y-axis. The recommended and standard classifiers have mean accuracy values of 93.6960% and 87.8230%, respectively.

5. Discussion

Through SPSS analysis on the outcome of group 1 and group 2, a mean accuracy of 93.6960% and 87.8230%, respectively, was obtained. Based on these experimental results, the proposed system is still considered the most efficient approach for identifying sales on bigmart.

Chose black friday [15] sale dataset and predicted black friday sale using Random forest classifier based on the root mean squared error. The suggested study detected sales with the accuracy of 83.6%. The author [7] processed structured data using ML classifier namely logistic regression and it attained prediction rate of 84% [11] performed comparative analysis of sales prediction on big markets using classifiers namely random forest and decision tree which attained accuracy of 83.96% and 81.21%. [2] chose Kaggle dataset for identification of back Friday sales on retail shops with observation counts 5,50,000 and 10 features. The analysis is carried out with two different ML classifiers namely linear regression and random forest the accuracy gain is calculated as 72% and 81%. [22] did analysis on customer's purchasing behavior based on time spent on a specific point to buy goods rather than spend time on the entire mall. The SVM classifier is chosen for this analysis which gains overall prediction accuracy of 81%.

XGBoost did not actually function effectively on sparse and unstructured data. As every classifier should rectify the errors caused by the preceding learners, a point that is usually ignored, gradient boosting is extremely sensitive to outliers. The strategy is rarely scaleable overall.

6. Conclusion

The utilization of machine learning techniques can be valuable in organizing data and decision-making. By implementing these new strategies, businesses can better understand consumer needs and develop effective marketing plans. The outputs of machine learning algorithms can help in selecting the most suitable algorithm for predicting demand, which Big Mart can use to plan its marketing activities.

116 Analysis of restaurant reviews using novel hybrid approach algorithm over support vector machine algorithm with improved accuracy

K. Abhilash Reddy[1,a] and Uma Priyadarsini P. S.[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

[2]Project Guide, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The proposed work will use a novel hybrid approach that incorporates components of the Support Vector Machine (SVM) algorithm to perform sentiment analysis on restaurant feedback. The objective is to develop a more accurate and efficient way of classifying the sentiment in restaurant reviews by combining the strengths of SVM with additional techniques for performance enhancement. Materials and Methods: This research suggests a novel hybrid approach based on deep learning to categorize restaurant evaluations into positive or negative polarities. To assess the suggested technique, a corpus of reviews is built. Result: The proposed Hybrid Approach Algorithm has been found to be more accurate than the Support Vector Machine (SVM) in analyzing restaurant reviews, with an accuracy of 96.1% compared to 94.89% for SVM. The difference in accuracy was statistically significant, with a p-value of 0.023 in which $p<0.05$. Conclusion: According to the evaluation findings on the test dataset, the Novel Hybrid Approach technique offers the highest level of review accuracy when compared to other methods currently in use.

Keywords: Sentiment analysis, novel hybrid approach, support vector machine, deep learning, restaurant reviews, polarity, food

1. Introduction

The importance of Machine Learning and Data Science in the restaurant industry can improve the customer experience and help the business grow. The applications of the analysis of restaurant reviews using the novel hybrid approach algorithm include. Improving Restaurant Operations: The analysis of customer feedback can be used by restaurants to identify areas for improvement and make informed decisions about menu offerings, service, and other aspects of their operations. The PSO algorithm streamlines the process of parameter tuning and optimization, resulting in improved performance measures. The PSO algorithm was then utilized to refine the results and achieve a higher G-mean. To overcome these issues, a hybrid strategy based on deep learning was presented for classifying the sentiment polarity into positive and negative. Another issue is lack of interpretability, some machine learning models, such as deep learning networks, can be difficult to interpret and making it challenging to understand the reasoning behind. The analysis's goal is to increase the categorization accuracy of restaurant reviews by substituting a novel hybrid approach algorithm for a conventional technique. In order to increase the accuracy of the results, the hybrid technique mixes two or more algorithms. The objective is to develop a system for sentiment analysis of restaurant evaluations that is more efficient.

2. Materials and Methods

In order to compare two controllers in supervised learning, this work is being carried out in the Machine Learning lab of the Saveetha School of Engineering at the Saveetha

[a]muralidharreddy273@gmail.com

Institute of Medical and Technical Sciences in Chennai. In this research work the dataset has been referred to from an article on restaurant reviews [6]. The sample size was determined through GPower software, where two groups of 10 sets were selected. GPower 3.1 software was used to calculate the pre-test power, with the settings set to a statistical test for the difference between the two independent means, =0.05 and power=0.80.

In this study, Technical Analysis software was used to create a Novel Hybrid method and SVM algorithm. Since ethical permission was not required, neither human nor animal samples were used. The hardware configuration included a 16 GB RAM and an Intel i5 core processor. HTML, Python, Java, Tomcat/Glassfish server, Jupyter notebook, My SQL database, CSS web technologies, and J2SDK1.5 Java version were among the programmes utilized.

2.1. *Novel hybrid approach algorithm*

The Novel hybrid approach algorithm for analyzing restaurant reviews combines multiple techniques from Natural Language Processing (NLP) to provide a comprehensive analysis of customer opinions and sentiments. The algorithm uses methods such as sentiment analysis, topic modeling, and entity recognition to identify trends and patterns in the data. The objective is to help restaurant owners and managers make informed decisions about their business by understanding the strengths and weaknesses of their establishment through the analysis of customer reviews. The insights obtained from the study can be used to improve the customer experience and enhance overall satisfaction.

Pseudocode for a hybrid approach algorithm for analyzing restaurant reviews:

Step 1: Pre-processing

Input: Raw restaurant reviews

Output: Cleaned and preprocessed reviews

Remove irrelevant information such as punctuation, stop words, and special characters.

Tokenize the reviews into individual words.

Perform stemming or lemmatization to reduce the words to their root form.

Step 2: Sentiment Analysis

Input: Cleaned and preprocessed reviews

Output: Sentiment scores for each review

To categorise each review as good, negative, or neutral, use a sentiment evaluation technique or model.

Calculate the sentiment score for each review based on the classification results.

Step 3: Topic Modeling

Input: Cleaned and preprocessed reviews

Output: Topics and their distributions in the reviews

Identify the topics by using a technique for topic modelling called Latent Dirichlet Allocation (LDA) to identify the primary topics discussed in the reviews.

Calculate the distribution of topics in the reviews.

Step 4: Entity Recognition

Input: Cleaned and preprocessed reviews

Output: Entities mentioned in the reviews

Use an entity recognition tool or model to identify entities such as food items, services, ambiance, etc. mentioned in the reviews.

Store the entities and their mentions in a data structure.

Step 5: Combination of Results

Input: Sentiment scores, topic distributions, and entity mentions

Output: Comprehensive analysis of the restaurant reviews

Combine the results from the sentiment analysis, topic modeling, and entity recognition steps to obtain a comprehensive analysis of the restaurant reviews.

Use the results to identify patterns and trends in the data.

Step 6: Visualization and Reporting

Input: Comprehensive analysis of the restaurant reviews

Output: Visualizations and reports

Use data visualization techniques to present the results of the analysis in an intuitive and easy-to-understand manner.

2.2. *Support vector machine algorithm (SVM)*

SVM is a type of supervised ML algorithm that can be used to analyze restaurant reviews and predict their sentiment (positive, neutral, or negative). The algorithm works by finding the best hyperplane to separate positive and negative reviews in a high-dimensional feature space. The SVM model identifies the hyperplane that maximizes the difference between the good and negative reviews using the reviews as vectors of characteristics, such as the presence of specific terms. The sentiment of new reviews can then be predicted by determining which side of the hyperplane they fall on. SVM can be an effective method for sentiment analysis in restaurant reviews, particularly when there is a limited amount of training data available.

Algorithm Steps

Step 1: Preprocess the data

- Clean and tokenize the reviews into a list of words

- Remove stop words, stemming/lemmatization

- Create a feature representation of the reviews (e.g. using bag of words or TF-IDF)

Step 2: Dataset Split into training and testing sets

- Randomly split the preprocessed reviews into a training phase and a testing phase

Step 3: Train the SVM model

- Initialize the SVM model with a suitable kernel and hyperparameters

- Fit the model to the training data, using the feature representation of the reviews as input and the sentiment labels as output

Step 4: Evaluate the model on the testing phase

- Use the trained SVM model to predict the sentiment of the reviews in the testing set

- To assess the performance of the model, calculate performance metrics including accuracy, precision, recall, and F1-score.

Step 5: Use the model to classify new reviews

- Preprocess and feature-represent the new reviews in the same way as the training data

- Trained SVM model will predict the sentiment of the customer reviews

2.3. Statistical analysis

When analyzing restaurant evaluations statistically, SPSS software employs a novel hybrid approach algorithm that outperforms the Support Vector Machine (SVM) method in terms of accuracy. Accuracy is the dependent variable, and effectiveness is the independent variable. A sample of 10 has been used for analysis. The Novel Hybrid Approach Algorithm's accuracy is calculated using the Statistical T test analysis.

3. Results

With a sample size of 10, the proposed Hybrid Approach Algorithm and SVM were run at various periods in the Jupyter Notebook. Table 116.1 represents the Hybrid Approach Algorithm's estimated accuracy and loss.

Table 116.2 represents the support vector machine loss and accuracy predictions (SVM). The statistical values that can be utilised for comparison are computed for each of the 10 data samples together with the associated loss values. According to the findings, Hybrid Approach Algorithm had a mean accuracy of 96.1% and Support Vector Machine had a mean accuracy of 94.89%.

Table 116.3 represents the average accuracy values for SVM and Hybrid Approach Algorithm (SVM). When compared to the SVM, the Hybrid Approach Algorithm's mean value is superior, with standard deviations of 1.11427 and 1.66248, respectively.

Table 116.4 depicts the independent sample T test results using the Support Vector Machine and the Hybrid Approach Algorithm, with a statistically significant value of 0.023 in which p<0.05.

Table 116.5 represents the comparison of the accuracy of the SVM and Hybrid Approach algorithms. The SVM has a 94.89% accuracy compared to the Hybrid Approach Algorithm's 96.10% accuracy.

Table 116.1. The Accuracy and Loss Analysis of Novel Hybrid Approach Algorithm for a sample size of 10. The Hybrid Approach Algorithm has an accuracy rate of 96.10% with loss rate as 3.90%

The mean accuracy of Hybrid Approach Algorithm is better than Support Vector Machine (SVM). X Axis: Hybrid Approach Algorithm vs Support Vector Machine (SVM) and Y Axis: Mean accuracy of detection with +/-2SD.

Source: Author.

When compared to the SVM Algorithm, the Hybrid Approach Algorithm performs more accurately.

Figure 116.1 shows a comparison between the Support Vector Machine and Hybrid Approach Algorithm's mean accuracy. The mean, standard deviation, and standard error mean for the Hybrid Approach Algorithm are 96.1000, 1.11427, and 0.35236, respectively. Support Vector Machine (SVM) has a mean, standard deviation, and standard error mean of 94.8930, 1.66248, and 0.52572, respectively.

The mean, standard deviation, and standard error mean are all given together with the group statistics value for the two algorithms. The accuracy levels of the Hybrid Approach Algorithm and Support Vector Machine (SVM) methods are contrasted and graphically represented for comparison. This demonstrates how much more accurate the Hybrid Approach Algorithm is, with 96.1% accuracy compared to SVM categorized accuracy of 94.89%.

4. Discussion

The hybrid approach combines two or more techniques to analyze the review text, such as sentiment analysis and opinion mining, to better understand the customer feedback. This research proposes a novel hybrid approach algorithm for analyzing restaurant reviews, which aims to improve the accuracy of predictions compared to a traditional Support vector machine algorithm. The main goal of the research is to provide more accurate and insightful analysis of restaurant reviews for decision-making purposes. 05 using the Support Vector Machine and the Hybrid Approach Algorithm. Additionally, a hybrid optimization strategy using PSO and SVM was used to determine the optimum weights and the k values for four distinct oversampling techniques to predict the reviews' sentiments [10, 21]. It was discovered the more consumers visit a restaurant's websites and physical locations the more good feedback it receives, which increases its popularity and success. The best part of this research is the development of a novel hybrid approach algorithm that improves the accuracy of restaurant review analysis compared to a traditional SVM algorithm. The limitations of the analysis of restaurant reviews using Hybrid Approach Algorithm over the SVM Approach Algorithm includes limited flexibility in handling non-linear data, poor performance in high-dimensional data sets, susceptibility to overfitting with large amounts of training data and requirement for significant computational resources for training and testing. The future scope of the analysis of restaurant reviews using machine learning includes Integration with other data sources. Machine learning models could be integrated with other sources of data, such as

customer demographics and menu item data, to provide more comprehensive analysis of restaurant reviews.

5. Conclusion

This research work proposes a Hybrid approach for the analysis of restaurant reviews. The Hybrid approach algorithm has a better accuracy of 96.10% when compared with the SVM algorithm (94.89%).

117 Effective prediction of IPL outcome matches to improve accuracy using novel random forest algorithm compared over logistic regression

Maturi Sai Girish[a] and P. Sriramya

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The objective of this study is to utilise the Novel Random Forest Classifier and the Logistic Regression algorithm to predict the winner of the IPL matches. This research provided the use of the IPL team's dataset. This study is divided into two groups, Novel Random Forest classifier and Logistic Regression Algorithm. Every group has a sample size of 10 and the study parameters are alpha rate 0.8 and beta value 0.2. The SPSS values were used to forecast the dataset's significance value with a G-Power of 80%. In IPL outcome predictor with significance value p=0.000 (p<0.05) shows the research is statistically significant and using the Novel Random Forest Algorithm got 98.55% higher accuracy than that of the Logistic Regression Algorithm with 77.82% accuracy. In IPL prediction, the Novel Random Forest algorithm got better accuracy when compared to the Logistic Regression algorithm.

Keywords: Cricket, IPL prediction, logistic regression, game, machine learning, novel random forest algorithm IPL matches, commercial enterprises

1. Introduction

Predicting the winner in IPL outcome matches involves analysing the game performed by the team members in addition to past matches they have played and their ability to play the game in previous matches. Cricket is the most popular sport in the world. The winning prediction has been done in an effective manner by the use of various systematic procedures in various formats. The IPL teams are chosen through an auction. It has a very high demand because of the game's popularity and the money at stake in this is very significant in comparison to other games. To win the competition, the best combination of players must always be assembled to get better returns for the commercial enterprises. The applications of the research include that IPL is a high-profile event, and advertisers are always looking for ways to reach out to their target audience. On the notion of IPL prediction, there are 20 research publications in Science Direct and 35 research papers in IEEE xplore. Malhotra employed six different machine-learning algorithms to forecast IPL outcomes and demonstrated the accuracy of matches played. They obtained the maximum accuracy of 87% for the novel random forest algorithm after utilising all six techniques, which is the best compared to all other algorithms. The overall goal of this research is to anticipate the percentage of Ipl outcomes matches. Singh examined the Ipl result matches game performance by team members using the smite and novel random forest algorithms. They segregated the data from the teams and applied a method to balance the datasets here. To predict IPL outcomes, balanced datasets are employed. Additionally, the Indian market is considered to be one of the fastest-growing markets in the world and has been attracting commercial enterprises in IPL matches and also in various sectors. This paper focuses on IPL teams and players. The research gap with present studies is that IPL prediction using novel random forest algorithms involves selecting relevant features that can improve the accuracy of the model. The aim of the research is to compare the accuracy of the novel Random Forest classifier and Gaussian NB Algorithm for IPL prediction.

2. Materials and Methods

Two groups were selected. The first group is the Novel Random Forest algorithm and the second group is the Logistic Regression algorithm. For each of the two groups, the sample size was taken as 10 [8]. For this research, work computation is performed using G-power as 80% with the confidence interval of 95%, alpha value 0.8 and beta value is 0.2. Here I used a collab notebook with Ryzen5processor, 8GB RAM, 64bit Microsoft Windows 11 operating system and other specifications required. To perform this work, I collected the dataset named as IPL prediction Dataset from a public domain named kaggle. It consists of 218 instances and total sample size is 436. The dataset was split into two parts training and testing. For training 80% of data is used and the remaining 20% was used for testing. By evaluating the train and test datasets the algorithms were implemented.

2.1. *Novel random forest (RF) algorithm*

It is an ensemble approach that integrates many decision trees to create a model that is more trustworthy and precise. Each decision tree in a random forest is constructed using a randomly chosen subset of features from the dataset. This lessens overfitting and enhances the model's capacity for generalisation. The approach additionally employs bootstrap sampling to generate numerous training sets that are then applied to the construction of various decision trees. When compared to other machine learning methods, random forest has a number of benefits. This technique can handle big datasets with plenty of features and is extremely accurate. Additionally, it can manage missing data without the need for imputation and is robust to outliers. Accuracy is defined as the ratio of accurate predictions to all other predictions. Equation 1 below is used to calculate accuracy.

$$Accuracy = TP + TN/TP + FP + TN + FN \qquad (1)$$

Where, TP = True Positive, TN = True Negative, FP = False Positive, FN= False Negative.

2.2. *Logistic regression (LR) algorithm*

The Logistic Regression Algorithm is the supervised Machine Learning (ML) algorithm that shines in many applications. The methodology applied on top of another ML algorithm is a Logistic Regression Algorithm. It is used for classification and regression. It involves three types of elements: weak base, strong base, and a loss function in ML algorithms. The typical decision tree is a weak model and composed of multiple weak models is a strong machine model. Logistic Regression Algorithm uses weak models into strong models iteratively. The best advantage of this algorithm is no need for new algorithms for each loss function that may want to be used. It must be differentiable because the loss function should be optimised. Evaluation of the Logistic Regression performance is done with an accuracy parameter, to find IPL prediction. The proportion of the total number of predictions that were correct to the total number of predictions is accuracy. The accuracy is calculated with given below equation 2:

$$Accuracy = \log(p/1-p) \qquad (2)$$

Here, Log(p/1-p) is an odd ratio.

3. Statistical Analysis

The software utilised for statistical implementation is IBM SPSS V22.0. The Statistical Package for Social Sciences (SPSS) is used for statistical computations such as mean and standard deviation, as well as graph plotting. Most runs average and teams are the independent variables. Matches and players is the dependent variable. The dataset is created with a sample size of 10 for each group with accuracy as the testing variable.

4. Results

The study is performed to predict the IPL using the Novel Random Forest Classifier and the LR and the performance measure is based on accuracy. The comparison of the novel RF model with the LR model revealed that the RF model had higher accuracy than the LR model. The mean accuracy of an RF model is 98. The standard deviation of an RF model is 0. 35720 between the RF model and the LR model. Because of the significant difference in variance, a Novel RF model is preferred. 1 the comparison of accuracy between the novel RF model and a LR model has been represented. The Novel RF model outperforms an LR model by a significant difference. Accuracy rates are compared for both an Novel RF model and a LR algorithm.

A confidence interval of the difference as lower and upper values range is shown in Table 117.7.

5. Discussions

Inside this research, a Novel RF with an accuracy of 98.55% significantly outperformed a LR model with an accuracy of 77.82% in determining IPL outcome attrition in Cricket matches [18]. Loss is also lower in the Novel RF model (Loss = 1.88%) than in the LR model (Loss = 22.17%).

Several of the research papers that have recently been published that support our research findings. The author's proposed methodology employs an RF model and the findings reveal that machine learning techniques outperform traditional methods for IPL prediction. In this paper, IBRF predicts Match attrition with the highest accuracy. For forecast user Match, an Novel RF model with the maximum accuracy was used. A Novel RF and relief LR model were tested and developed to predict user attrition, based on the author. Novel RF models are much more accurate as relief LR models. When the author merged two models, he improved his reliability. As compared to other models, the Novel Random forest and LR classifier have the higher precision with an AUC score of 84% for Match prediction. When the author combined two models, he improved his accuracy. There are some papers opposed to my research findings. In the future, the authors plan to increase the performance of the established model by including more features and assessment parameters, as well as proposing new models based on convolutional neural networks. Complexity of IPL outcome matches, IPL matches outcome can be complex and varied and it can be challenging to identify the specific factors that contribute to match. In future, the

accuracy of the prediction model can be improved by integrating it with other data sources such as social media, weather data, and player injury reports.

6. Conclusion

The current experimentation study aims to increase the accuracy of IPL victory prediction. The Novel Random Forest method is compared to the Logistic Regression technique in this research study. The collected results revealed that the Novel Random Forest method offered an accuracy of 98.65% and the Logistic Regression algorithm produced an accuracy of 77.82%.

Abstract: The purpose of this research is to use the Novel Random Forest Classifier and the Gradient Boosting Classifier algorithms to predict the winner of the IPL matches. This study will make use of the team players dataset. This research is divided into two groups: Novel Random Forest classifier and Gradient Boosting Classifier Algorithm. Each group has a sample size of 10, and the study parameters are alpha value 0.8 and beta value 0.2. The SPSS values were used to forecast the dataset's significance value with a G-Power of 80%. The statistical significance value p=0.000 (p<0.05) achieved for IPL outcome predictor signifies that there is strong significance as the statistical significance is achieved to be p=0.000 (p<0.05) over the two algorithms. For IPL forecasting the Novel Random forests algorithm gives the accuracy of 98.65.% which is more effective than the Gradient Boosting Classifier Algorithm, which is 83.68%.: In IPL forecasting, the algorithm for Novel random forests surpasses the Gradient Boosting Classifier Algorithm.

Keywords: Machine learning, cricket tournament, commercial enterprises, match outcome prediction, novel random forest algorithm, gradient boosting classifier, IPL matches

1. Introduction

Determining the winner in IPL outcome matches includes assessing the game performed by the team members as well as past games they had played and their ability to play the game in previous matches [7]. Cricket is the most popular sport on the planet. The tournament is known for its high-energy matches and nail-biting finishes, making it one of the most popular sporting events in the world and the investment done by the Commercial enterprises. With so much excitement and unpredictability, it can be challenging to predict the outcome of each match. It has a higher value because of the game's popularity and the money involved in it is very significant when compared to other games. The best fit of competitors must be established in order to win the competition. The application

of the research is that the Random forest algorithm can be trained on past IPL data to predict which player is likely to score the most runs in a particular match. The algorithm can take into account factors such as the player's past performance, batting position, and the opposition's bowling strength to make the prediction. Machine learning algorithms have been used to predict the cricket tournament game, and the best approach to predict the game is the Novel Random forest, Logistic Regression, and their results can be compared over the Evaluation Measures such as accuracy, precision, recall, sensitivity, and error rate. Many papers about IPL prediction have been written in recent years [5]. The records that have been compiled from previous performances and data can be used to predict the winning team. On the notion of IPL outcome prediction, there are 856 research publications in Science Direct

and 564 research articles in IEEE xplore.projected the winner of the IPL matches using the novel random forest method. The data is then divided into model acts and reactions. The present research gap is that IPL prediction utilising the innovative novel random forest technique comprises the selection of important characteristics that may improve the model's accuracy.

2. Materials and Methods

The Novel Random Forest algorithm is in the first group, and the Gradient Boosting Classifier algorithm is in the second [8]. The sample was set at ten for each of the two groups. For this study, work is computed using G-power of 80% with a standard error of 95%, alpha value, and beta value of 0.2. A colab notebook with a Ryzen 5 processor, 8GB RAM, 64bit Microsoft Windows 11 software, and other characteristics was employed in this case. To do this job, I obtained the dataset titled IPL Prediction Dataset from the public domain kaggle. It has 218 instances with a total sample size of 436. The dataset was divided into two sections: training phase. 80% for training of data is used and the remaining 20% was used for testing. By evaluating the train and test datasets the algorithms were implemented.

2.1. Novel random forest algorithm (RF)

A Novel RF algorithm is the most often used supervised learning model. Each decision tree is built by the method using a subset of characteristics and data from the dataset that are randomly chosen. By doing this, it lessens overfitting and enhances the model's generalizability. With the ability to handle both mathematical and categorical input, random forest is frequently employed for regression and classification queries. It has been effectively used in a variety of industries, including marketing, healthcare, and finance. The capacity of random forest to produce feature

significance ratings, which can aid in determining the most important predictors of the variable of interest, is one of its main advantages. Accuracy is determined by dividing the overall amount of predictions by the proportion of accurate predictions. Equation 1 shown below is used to determine accuracy.

$$Accuracy = TP + TN/TP + FP + TN + FN \qquad (1)$$

Where, TP= True Positive, TN= True Negative, FP= False Positive, FN= False Negative

2.2. Gradient boosting classifier (GBC)

It is one of the techniques of providing the best accuracy for predicting the IPL outcome matches with help of the certain datasets to provide the accurate results. It is used for classification and regression. It involves three types of elements: weak base, strong base, and a loss function in ML algorithms. The typical decision tree is a weak model and composed of multiple weak models is a strong machine model. It supports so many functions like squared error for a regression problem and logarithmic loss for classification problems. Evaluation of the Gradient Boosting Classifier performance is done with an accuracy parameter, to find IPL prediction. The proportion of the total number of predictions that were correct to the total number of predictions is accuracy.

3. Statistical Analysis

The software utilised for statistical implementation is IBM SPSS V22.0. The Statistical Package for Social Sciences (SPSS) is used for statistical computations such as mean and standard deviation, as well as graph plotting. Most runs average and teams are the independent variables. Matches and players is the dependent variable. The dataset is created with a sample size of 10 for each group with accuracy as the testing variable.

Table 118.1. Sample dataset containing independent values

Figure 118.1. Comparison of novel RF algorithm and Gradient Boosting Algorithm in terms of mean accuracy and mean loss. The mean accuracy of a novel RF algorithm (96.65%) is better than Gradient Boosting Classifier (83.68%) and the standard deviation of a novel RF algorithm is slightly better than the Gradient Boosting algorithm. X-Axis: RF algorithm vs Gradient Boosting algorithm. Y-Axis: Mean Accuracy and Mean Loss of detection = +/- 2 SD.

Source: Author.

higher accuracy than the Gradient Boosting model. The novel RF algorithm outperformed the Gradient Boosting classifier algorithm. The mean accuracy of a novel RF model is 98. A novel RF model has a standard deviation of 0. The standard error mean for an Novel RF model is 0. The t test for equality averages revealed that the Novel RF model and the Gradient Boosting Classifier model had a mean difference of 14. A Novel RF model is preferred because of the significant difference in variance. Table 118.7 shows a confidence interval for the difference as a lower and upper value range.

5. Discussions

In this analysis, an Novel RF model with an accuracy of 98. 65% outperformed a GBC model with an accuracy

of 83. The RF model likewise has a smaller loss than the GBC model. Several recent research papers have been released that support our research results. The proposed methodology by the author incorporates a novel RF model, and the results show that machine learning techniques beat traditional methods for IPL prediction. The author discusses an IBRF model. The author discusses an IBRF model. IBRF predicts Match attrition with the highest accuracy in this paper. Relief GBC models are far more accurate than novel RF models. When compared to other models, Novel Random Forest and Gaussian NB classifiers offer the highest precision for Match prediction, with an AUC score of 84% [20]. Predicting the outcome of IPL matches can be difficult. The accuracy of the prediction model may be improved in the future by combining it with new data sources such as social media, weather data, and player injury reports. This will help gather the most up-to-date data and produce more accurate forecasts.

6. Conclusion

The findings of this study demonstrate the high accuracy of our proposed innovative RF model, which can be utilised to forecast IPL matches with a 98.65% improvement in accuracy over the Gradient Boosting Classifier model's accuracy of 83.68%.

119 Comparison of hybrid regression model with smoothed moving average model for demand forecasting of product

Adibhatla Ajay Bharadwaj[a] and M. Gunasekaran

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The main goal of this research is to predict the forecasting trends for a demand of a product by using the novel hybrid regression (NHR) machine learning model and historical sales data in comparison with the Smoothed moving average model (SMMA) to produce accurate results. Materials and Methods: The dataset employed in this research is store item demand forecasting dataset. The original data is partitioned in two different groups and each group consists of a sample size 20. In this study the final sample size calculation is done with a G-power pretest of 80%, threshold 0.05% and CI-95%. Results: The observed outcome after calculating the accuracies is that the novel hybrid regression model with 84.16% has shown a better confidence than the smoothed moving average model with 68.35%. There exists a statistical significance between NHR and SMMA in accordance with the sample t-test with the numerical value of p=0.000 (p<0.05) two-tailed. Conclusion: The result shown in this study significantly proves that the novel hybrid regression model shows a better accuracy in predicting the demand forecasting trends for demand of a product.

Keywords: Demand forecasting, machine learning, novel hybrid regression model, product, retail business, smoothed moving average

1. Introduction

This research study has shown prediction of the demand forecasting trends of a product by using novel hybrid regression machine learning model and the store item demand forecasting dataset. It allows the retailers to conduct a proper system to ensure that product inventory is neither greatly over-stocked and surpasses the requirement or understocked and is available below the required quantity [14, 22]. By having the knowledge on the demand forecasting trends of a product the growth rate of the retail business can be determined and an efficient growth strategy can be planned [26]. The applications of the product demand forecasting include that it provides an optimal support for maintaining the economical efficiency of the retail business, it plays a major role in production planning and inventory management. Numerous research papers have been published on demand forecasting and some amount of the research has been done on retail business product demand forecasting. The research articles

done on product demand forecasting are published across various different websites and publications. In comparison of all the research the study is the best and shown better model performance and prediction accuracy. The proposed model and algorithms in the existing research have not been accurate in forecasting the results. The research is vague, makes irrational assumptions, and the data analysis is inaccurate. The primary aim of this research is to predict the forecasting trends of product demand using the navel hybrid regression machine learning model to obtain accurate results.

2. Materials and Methods

This research investigation was conducted at the Computer Communication Lab, within the premises of the Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, located in Chennai. This research has two sample preparation groups. Each group comprises a sample size of 20 records with

the total sample size of 40 [4, 5]. The final sample size has been calculated with a G-power pre-test score of 80%, beta value of 0.15, alpha as 0.05 and CI - 95%.

The software components used in this study are jupyter notebook, IBM SPSS version 26.0.1 and the hardware component include a laptop with a configuration of 16 GB ram with an intel 9th gen i5 processor and a 4GB graphic card. The store item demand forecasting dataset [9] mainly consists of five columns namely date, store, item, sales and id. The original dataset is scaled down to the sample size of 538 by using slicing, then the data is tested using python libraries in the jupyter notebook code environment. The dataset is collected from kaggle.com.

2.1. *Novel hybrid regression model*

The novel hybrid regression model employs regression modeling as well as EDA data analysis. The data is then made stationary using statistical forecasting. The Xgboost algorithm is used in the implementation of time series forecasting using regression modeling, and in this model, the Xgboost regressor uses gradient boosting to forecast product demand. The initial store item demand forecast dataset, which is a time series data, will be transformed into supervised data. The data will be made stationary after being transformed. This model takes a more direct path to reduce error, quickly converge data, and simplify calculations. To forecast the values of the dependent variables, the model employs a number of gradient boosted trees. Combining decision trees to create a combined strong learner is how this is accomplished; the gradient boosted trees in this context refer to the values of the model's n estimators.

Algorithm
Input: Retail store product historic demand data
    Step 1: Use the necessary packages
    Step 2: Setup the programming environment and import the data set and store it in a data frame
    Step 3: Apply statistical forecasting
    Step 4: Implement trend and seasonality constraints
    Step 5: Convert forecasted values to original scale
    Step 6: Convert the data to be stationary
    Step 7: Generate a data frame for data transformation from time series to supervised
    Step 8: Generate a lag column
    Step 9: Separate the train and test data
    Step 10: Use the minmax scalar to scale the data
    Step 11: Yield X_train, Y_train, X_test, Y_test values
    Step 12: Implement reverse scaling
    Step 13: Obtain the prediction values and store it in pred dataframe

    Step 14: The results forecasted using XGboost regressor
    Output: Future demand of retail products forecasted

2.2. *Smoothed moving average*

The smoothed moving average algorithm predicts and forecasts the trends based on the average of demand in the past. The model takes all the historical data and converts it into a supervised problem data. Then it transforms that data to a stationary state and adjusts the trend and seasonality constraints for the time series data. Then it calculates a series of averages from the transformed historical data and forecasts the future prediction using the average of the trend. It serves as a valuable tool for analyzing sales trends over an extended period and assisting in long-term demand forecasting.

In case of any quick changes in demand due to availability and seasonality of the product are smoothed out in this model, so the final prediction can be done more accurately. This model uses this smoothing method of data in consideration of factors influencing the demand.

Algorithm
Input: Retail store product historic demand data
    Step 1: use the needed packages
    Step 2: load the dataset into the code environment
    Step 3: Plot the data and understand the observation
    Step 4: Use the smoothing technique in data preparation in order to reduce random variation
    Step 5: Use rolling function to group observations
    Step 6: calculate the moving average of the supervised data
    Step 7: Add the calculated data as a new input feature
    Step 8: Create a lag column and store the data
    Step 9: Adjust the trend and seasonality components of the original time series data
    Step 10: Predict and forecast using moving average model
    Output: Future demand of retail products forecasted

2.3. *Statistical analysis*

The statistical analysis is carried out using the IBM SPSS 26.0.1 software for both the proposed model and the compared model. The sales and item columns in this dataset are the dependent variables. The store, date and item columns in this dataset are independent variables. The analysis done in this study is an independent sample T test analysis. This analysis is done on both the models. After analyzing the mean accuracy, standard deviation, standard error are noted.

3. Tables and Figures

Table 119.1. The Group statistics of the data was performed for 20 iterations between novel hybrid regression algorithm and smoothed moving average model. The novel hybrid regression model (84.61%) outperforms the SMMA model (68.35%)

	Group	*N*	*Mean*	*Standard Deviation*	*Standard Error Mean*
Accuracy	NHR	20	84.61	4.971	1.112
Accuracy	SMMA	20	68.35	4.934	1.103

Source: Author.

Table 119.2. The independent sample t-test was performed between NHR and SMMA for 20 iterations with the confidence interval of 95% and the level of significance p=0.000 (p<0.05) two-tailed, this shows that there is a significance between the two groups

		f	*sig*	*t*	*df*	*T-test for Equality of Means* *Sig. (2-tailed)*	*T-test for Equality of Means* *Mean Difference*	*T-test for Equality of Means* *Std. Error Difference*	*T-test for Equality of Means* *95% Confidence interval of difference*
Accuracy	Equal variances assumed	.100	0.754	10.381	38	.000	16.2600	1.5663	19.4308
Accuracy	Equal not variances assumed			10.381	37.998	.000	16.2600	1.5663	19.4308

Source: Author.
Figure 119.1. Comparison based on mean accuracy of the Hybrid regression algorithm (84.61%) to the SMMA algorithm (68.35%), it is evident that the Hybrid regression algorithm outperforms the smoothed moving average algorithm. The X-axis represents the comparison between NHR and SMMA algorithms, while the Y-axis represents the mean accuracy. Error bars indicate a range of +/-2 standard deviations.

Source: Author.

4. Results

After comparing and analyzing the both models it is observed that the novel hybrid regression model has significantly outperformed the smoothed moving average model in prediction of forecasting trends for demand of product.

In Table 119.1 the group statistical analysis is performed for both models on all iteration variables. The proposed novel hybrid regression model has outperformed the smoothed moving average model. The mean accuracy of the novel hybrid regression model observed is 84.61% and for the smoothed average model is 68.35. The standard deviation observed for the novel hybrid regression model is 4.9711 and for the smoothed moving average model is 4.9349. The mean standard error observed in novel hybrid model is 1.1116 and in smoothed moving average model is 1.1035.

In Table 119.2 the independent Sample T test is performed on both the proposed model and compared model. The significance value shown on the equal variance of 0.754 for the test performed. The novel hybrid regression model is better because of the significant difference in variance. The mean and standard error difference is equal for both the novel hybrid model and smoothed moving average model. At 95% confidence interval of the difference both the lower interval and upper interval values are the same.

Figure 119.1 shows the graphical representation of the accuracy difference between the novel hybrid regression model and the smoothed moving average model. It can be viewed that the novel hybrid regression model has shown a good difference in accuracy compared to smoothed moving average model.

5. Discussion

Through the research conducted in this study, a novel hybrid regression model was developed, achieving a noteworthy level of accuracy 84. 61% has shown a better performance compared to the smoothed moving average model which has an accuracy of 68. In he author's proposed a model that performs the best forecasting with a 42. 4% MAPE score on average, the author's proposed model uses the gradient boosting method and has shown a good prediction and forecasting of the demand data in the fashion industry, the author's proposed study uses a GBT model for predicting the forecasting trends of demand, the observed RMSE score is 2. 299, the author's proposed neural network model has shown a decent accuracy for the forecasting prediction demand in anti aircraft missiles [2, 20, 25] the author's proposed model has shown a MAPE value of 14% in demand forecasting. There is no research published opposing the proposed algorithm and model. The store item forecasting dataset consists of data regarding only retail business products, and it contains data of around 30 products, so the model can only predict the forecasting of demand for only these products. The dataset is limited so the model will be unable to predict various kinds of products across different industries. Improve the dataset by adding more products and different kinds of products from various industries to increase the prediction scope of the model.

6. Conclusion

In this study the novel hybrid regression model has been compared to the smoothed moving average model for predicting the forecasting trends of product demand. The novel hybrid regression model had better performance with an accuracy difference of 16.26% than the compared model.

120 Comparison of improved XGBoost algorithm with random forest regression to determine the prediction of the mobile price

Nallabothu Vamsi Priya[a] and S. TamilSelvan

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai, India

Abstract: Aiming to predict mobile prices using Improved XGBoost Regressions and comparing them with Random Forest Regressions has been the focus of this study. Materials and Methods: For this research to evaluate the prediction results obtained from Improved XGBoost algorithm and Random Forest Regression on 20 samples. Each sample size is calculated with a data set size of 95,650 using ClinCalc software with 0.05 as the alpha value, and a Confidence Interval (CI) of 95%. We used Kaggle.com data for this research and attributes like smartphone size, model, and brand were included. Results: According to SPSS statistical analysis, the algorithm used by Improved XGBoost differs statistically significantly from Random Forest Regression, with P=0.001 (Independent Sample t-Test P=0.05). The accuracy of the Improved XGBoost method is 97.37%, which appears to be superior to Random Forest Regression of 95.00% correspondingly. Conclusion: The Improved XGBoost Regression gives the best output when compared with Random Forest Regression for mobile price prediction in terms of accuracy.

Keywords: Forecast, mobile price, machine learning, improved XGBoost, phone services, random forest regression, regression

1. Introduction

Extreme gradient boosting regression, used in mobile price prediction, increases pricing accuracy in comparison to random forest regression. For the purposes of this research, predicting the price of a mobile phone is vital [5]. Mobile phones come in a wide variety of prices, features, and other phone service requirements. New and frequently updated mobile devices with new capabilities are available on the market [6, 15]. In the phone services, hundreds of mobile phone services are sold each day. In such a volatile and fast-paced market, a mobile carrier must establish the most competitive pricing to compete with its rivals [2]. The initial step in determining pricing is to calculate a price based on features. Obtaining an estimate of the cost of a mobile phone service based on its characteristics is the objective of this project. Predicting future mobile prices is the purpose of using mobile price prediction [8].

The price of mobile phones has reportedly been predicted by researchers. IEEE Digital Xplore has published 80 articles related to that research, Science Direct has published 80 articles, Google Scholar has published 120 articles, and SpringerLink has published 12,305 articles [11]. Mobile phones are handheld communication devices that enable people to make and receive calls wirelessly [12]. They can now support web browsers, games, cameras, video players, and navigational systems [13, 16]. The major objective of this study is to more accurately forecast the price of mobile in the future. The greatest journal to read for my project is this article about applying machine learning to anticipate mobile prices, and it is available on Google Scholar [4]. The forecasting of mobile prices is the research gap that has highlighted lack of accuracy in the forecasting of mobile prices. For mobile price forecasts, we used Improved XGBoos Algorithm [4] and

Random Forest Regression. The goal of this work is to anticipate the prediction accuracy of cellphone prices by utilizing an improved XGBoost algorithm and contrasting the results with Random Forest Regression.

2. Materials and Methods

We were working in the Soft Computing Laboratory of the Saveetha Institute of Medical and Technical Sciences, Saveetha School of Engineering, to carry out this research. The inquiry involved consultation with two groups. Improved XGBoost Regression and Random Forest Regression make up our two groupings. Ten samples are presented in each category [3]. The calculation is done with a G-power of 80%, with an alpha value of 0.05 and a 95% confidence level. The two methods utilized in this study are Improved XGBoost Regression and Random Forest Regression. The Mobile Price dataset is used to determine mobile device costs. The price analysis dataset with a size of 95,650 was considered from Kaggle repository [10]. The dataset contains thirteen attributes, such as Product_ID, Price, Sale, Weight, Resolution, PPI, CPU Core, CPU Freq, Interval Mem, Ram, Rear_Cam, Front_Cam, Battery, and Thickness. There are ten samples taken from each group. The dataset is divided into training and testing data. Ten samples are taken of test data and training data. The dataset is divided, and the method is fitted to the training and test sets to forecast accuracy values.

2.1. Improved XGBoost regression

A networked, scalable gradient-boosted decision tree (GBDT) machine learning framework is called Extreme Gradient Boosting (Improved XGBoost). It provides parallel tree boosting and is the best machine learning package for regression, classification, and ranking problems. Understanding the machine learning principles and methods on which ensemble learning, gradient boosting, decision trees, and supervised machine learning are based is crucial to understanding Improved XGBoost. In supervised machine learning, a model is trained using algorithms to find trends in a dataset of features and labels, after which the model is applied to forecast the labels on the features of a new dataset.

Procedure
Input: Dataset k
    Output: A testing dataset class
    Step 1: First step is to input the dataset.
    Step 2: Process the dataset.
    Step 3: Apply the datasets and define the Extreme Gradient Boosting parameters to it.
    Step 4: Define the mean and metrics values to ot.
    Step 5: Finally, cross-validate the dataset

2.2. Random forest regression

A collection of classification accuracy-improving learning algorithms. A supervised machine learning approach called random forest functions as a sizable collection of de-correlated decision trees. Machine learning techniques that use decision trees make up the "forest" that the program creates. Out of the entire set of data, the algorithm generates random values. It builds a decision tree from each subgroup using a bootstrap sample for each tree. It builds many decision trees and blends the outcomes. The train data set is used for the bootstrap sampling. To construct the tree, a fresh sample is picked each time. This adds unpredictability, which raises the model's bias and lowers its variances. Prevents a model from overfitting, which is a problem with decision trees. Produces generalized models that perform far better.

Procedure
1. Randomly select K data points from the training set.
2. Create decision trees for the selected data points.
3. Select an N to represent the number of decision trees intended to create.
4. Repeat steps 1 and 2.
5. Determine each decision tree forecast for new data points, then assign the new data points to the category that has received the most votes.

3. Tables and Figures

Table 120.1. The accuracy results indicate that the Improved XGBoost Regressor outperforms the Random Forest Regression algorithm. Specifically, the XGBoost model achieved an accuracy of 97.37%, while the Light GBM (LGBM) model achieved an accuracy of 95.00%

Samples	XGB	RFR
1	97.00	95.00
2	97.12	94.99
3	96.99	94.99
4	96.99	94.90
5	96.95	94.95
6	97.00	95.12
7	97.00	95.00
8	96.97	95.00
9	96.99	95.05
10	96.99	95.00

Source: Author.

Table 120.2. The group, mean and standard deviation, as well as the accuracy of the Improved XGBoost and Random Forest Regression, were as follows: XGB has a mean accuracy (97.37), standard deviation (0.04497), and RFR has a mean accuracy (95.00), standard deviation (0.05735)

Group Statistics					
	Group	*N*	*Mean*	*Std. Deviation*	*Std. Error Mean*
Accuracy	XGB	10	97.00	0.0497	0.01422
	RFR	10	95.00	0.05735	0.01814

Source: Author.

Table 120.3. An independent sample T-test with P=0.001 (Independent Sample t-Test P0.05) can be used to analyze the significant difference between the Improved XGBoost algorithm and Random Forest Regression

Independent Samples Test										
		Levene's Test for Equality of Variances		T-test for Equality of Means					95% Confidence Interval of the Difference	
		F	*Sig*	*t*	*df*	*Sig (2-tailed)*	*Mean Difference*	*Std. Error Difference*	*Lower*	*Upper*
Accuracy	Equal variances assumed	0.295	0.594	86.78	18	0.001	2.0000	0.02305	1.9515	2.0484
	Equal variances not assumed			86.78	17.03	0.001	2.0000	0.02305	1.9513	2.0486

Source: Author.
Figure 120.1. In terms of mean accuracy and mean loss, the Improved XGBoost Algorithm (97.00%) outperformed Random Forest Regression (95.00%). The mean accuracy of an Improved XGBoost Algorithm is higher than that of Random Forest Regression, and the standard deviation of an Improved XGBoost Algorithm is slightly lower than that of Random Forest Regression.

Source: Author.

4. Results

Table 120.1 represents the parameter used here for accuracy, this parameter is used for regression techniques, and Improved XGBoost and Random Forest Regression are proposed with 10 times iteration accuracy values for iterations of XGB 97.37% and RFR

95.00%. Compared to Random Forest Regression, Improved XGBoost Regressor looks to perform significantly better.

Table 120.2 Represents the outcomes of the group statistics provided with XGB having a mean accuracy of 97.37% and a standard deviation of 0.04497. The mean accuracy of RFR is 95.00%, while the standard deviation is 0.5735. The suggested Improved XGBoost performance outperforms the RFR.

Table 120.3 represents the P=0.001 (Independent Sample t-Test P<0.05), the results of the independent sample T-test that may be used to determine if there exists a significant difference between the Improved XGBoost algorithm and Random Forest Regression.

Figure 120.1 shows the average accuracy for the XGB and RFR algorithms using a bar graph. With +/- 2SD, RFR and XGB both have an average 95% detection accuracy.

4.1. Statistical analysis

SPSS was used to analyze descriptive statistics for the Improved XGBoost Regressor and Random Forest Regression. In this dataset, the product _id and weight are utilized as independent variables, and the price is used as a dependent variable. A t-test using independent samples was done [1].

5. Discussion

Based on the findings of this study, it was found that Mobile Price Prediction using the Improved XGBoost regression method is a much more accurate method than Random Forest Regression with 97.37% and 96.67% accuracy, respectively. The results obtained with the use of Improved XGBoost are more consistent, and the standard deviation of the results is smaller.

Random forest regression is the planned work of reported Improved XGBoost current work. Which uses the features and specifications to anticipate the pricing of mobile devices [7]. The precision desired only occasionally results from increasing the dataset's value (United States Federal Communications Commission 2017). Combining improved XGBoost with other machine learning methods results in improved performance [9]. The use of this kind of forecast helps companies to estimate the price of mobiles to give tough competition to other mobile manufacturers in phone services [14], also it would be useful for consumers to verify that they are paying the best price for a mobile.

The drawback of this investigation is that it comes into problems when there are more predictions than data. One is chosen at random if it includes two or more highly correlated variables. Prone to explode as a concern. If the correct results are not produced for smaller data sets and not all training parameters are taken into account. As the field of mobile phone services forecast expands and changes in the future, customers and company partners will have greater opportunities to keep on top of trends and make knowledgeable choices about mobile pricing prediction using regression and the more precise Improved XGBoost.

6. Conclusion

Improved Extreme Gradient Boosting Regression and Random Forest Regression are the two approaches used in this study to accomplish the Mobile Price Prediction. While the RFR accuracy score is 95%, the Improved XGBoost accuracy value is 97.37%. Compared to the Improved XGBoost Regression, RFR seems to be less accurate. Improved XGBoost Regression seems to perform noticeably higher than random forest regression for Mobile Price Prediction.

121 Efficient of cursive character recognition in IOT using CNN compared with ANN with improved accuracy

B. Naveen Kumar Reddy[a] and Mahaveerakannan R.

Department of Artificial Intelligence, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The ability of a computer to gather and analyze legible handwritten input from a range of sources, such as paper documents, images, touch displays, and other devices. These sources can be read by the computer. This work is being done with the intention of enhancing character recognition in cursive writing. The OCR technology available today has an accuracy rate of more than 80, when analyzing typed letters in photographs of excellent quality. When it comes to detecting cursive characters, novel CNN and ANN are both put through their paces using a wide variety of departments devoted to training and examination. The Gpower test that was carried out had a significance level of around 85% 0.85 power, and 0.05 g power are the criteria for setting up g power. Novel CNN (91.8460%) has increased accuracy over ANN (84.4000%) which is equivalent to 0.001 in terms of the level of significance (p < 0.05). The accuracy of novel CNN is better when compared to accuracy of ANN.

Keywords: Artificial neural network (ANN), novel convolution neural network (CNN), IOT, optical character recognition, accuracy

1. Introduction

The fragmentation of interacting cursive characters is the primary bottleneck in this procedure, which explains why the reliability rate is so low. One of the reasons why are taking this particular strategy is because of this. In this article, provide an effective method for offline categorization of cursive touched characters that is built on the examination of pixel intensities. The fact that a machine is able to read handwriting is shown by this offline method of handwritten character recognition [19]. The major purpose of a cursive character recognizer, which also has a variety of additional implementations, is the capability to convert handwritten signatures and observations into text that can be modified. The study of recognizing cursive characters has resulted in the publication of an average of 558 research papers in the database known as IEEE Xplore and 36 journals in the database known as Science Direct. Both the Chars74K and the ICDAR03 datasets have been used in order to accomplish the goal of assessing the model that has been suggested. Employ a method known as the

"histogram of oriented gradients" approach in order to evaluate how well the suggested model performs in comparison to the recently produced Urdu character image dataset. Because of this, are better able to validate the model that was provided [11]. The aim of this study is to evaluate how the accuracy of classification may be improved by using novel convolutional neural networks and compare its effectiveness with that of an artificial neural network. The paradigm that was recommended makes the recognition of cursive characters simpler.

2. Materials and Methods

The research was carried out at the Soft Computing Lab, which may be found in the same building as the college that bears its name. By comparing the performances of the two controllers, the appropriate size of the sample has been calculated with the assistance of the Gpower software. The method is carried out on two separate sets of participants, and the results obtained from each set are analyzed and compared.

This task calls for the selection of 10 different samples from each group, making the total number of samples required for each group 10. 85, determined that the optimal number of samples for each group was 10. Python OpenCV is helping to produce and carry out the work that is being recommended. Python OpenCV is helping to create and carry out the work that is being suggested. As the investigation and assessment platform for deep learning, the Windows 10 operating system was used. Java was chosen as the language of choice for the implementation of the code, and it was this language that was used. During the process of the code being run, the dataset is being worked through in the background so that an output process may be carried out and checked for accuracy.

3. Description—Novel CNN

3.1. Pseudocode

Novel convolutional neural networks (CNN) are a specialized kind of network architecture that was developed specifically for use with deep learning algorithms. Image recognition and other operations that involve the computation of pixel input are examples of the sorts of tasks that make use of novel convolutional neural networks (CNN). Novel convolutional neural networks (CNN) were structured for use with deep learning algorithms. The categorization of photographs, the identification of faces, the location of objects, and many other computer vision applications all make use of convolutional neural networks. These networks are also utilized in a broad range of other computer vision applications.

Step 1: Load the training and testing dataset of cursive handwriting images and their corresponding labels

Step 2: Preprocess the data by reshaping the input data and one-hot encoding the labels

Step 3: Define the CNN model using the Keras Sequential API

a. Add a Conv2D layer with 32 filters, a 3x3 kernel, and ReLU activation, with an input shape of (28, 28, 1).
b. Add a MaxPooling2D layer with a 2x2 pool size
c. Add a Conv2D layer with 64 filters, a 3x3 kernel, and ReLU activation
d. Add another MaxPooling2D layer
e. Add a Conv2D layer with 128 filters, a 3x3 kernel, and ReLU activation
f. Add another MaxPooling2D layer
g. Add a Flatten layer to flatten the output of the previous layer
h. Add a Dense layer with 256 neurons and ReLU activation

i. Add a Dropout layer with a rate of 0.5 to prevent overfitting
j. Add a Dense layer with 26 neurons and softmax activation, representing the 26 classes of characters

Step 4: Compile the model using the Adam optimizer and categorical cross-entropy loss

Step 5: Train the model using the fit method with the preprocessed training data and labels, specifying the number of epochs, batch size, and validation split

Step 6: Evaluate the model on the preprocessed test data and labels using the evaluate method

Step 7: Print the test loss and accuracy

3.2. Description—ANN

Artificial neural networks, often known as ANNs, are a kind of algorithm that are patterned after the way in which the information processing occurs in the human brain. They are able to simulate difficult patterns and provide solutions to complex prediction issues. Processing happens one record at a time, and the system learns by comparing its own (mostly arbitrary) categorization of the information being analyzed to the actual categorization of those documents. This happens record by record.

Pseudocode:

Step 1: Import the required libraries: OpenCV and TensorFlow.

Step 2: Load the pre-trained machine learning model for cursive handwriting recognition.

Step 3: Load the image of the cursive handwriting for recognition.

Step 4. Perform image pre-processing on the loaded image using the following steps:

a. Apply Gaussian blur to smooth the image and reduce noise.
b. Apply Otsu's thresholding to binarize the image.

Step 5. Extract features from the pre-processed image using the following steps:

a. Use the OpenCV "findContours()" function to find contours in the image.
b. For each contour found, get its bounding box coordinates.
c. Extract the region of interest (ROI) from the image using the bounding box coordinates.
d. Resize the ROI to the size expected by the model (28x28).
e. Normalize the ROI pixel values to be between 0 and 1.
f. Reshape the ROI to be compatible with the input shape of the model (1x28x28x1).

Step 6: Use the trained machine learning model to predict the class of each extracted ROI.

Step 7: " Convert the predicted class index to its corresponding character using the "chr()" function."

Step 8. Draw the predicted character on the original image using the OpenCV "putText()" function.

Step 9: Display the output image using the OpenCV `imshow()` function.

Step 10. Wait for user input to close the displayed image using the OpenCV "waitKey()" function.

Step 11. Close all open windows using the OpenCV "destroyAllWindows()" function.

3.3. Statistical analysis

The regression equation that the novel Convolution Neural Network (CNN) and ANN [21] do is done with the help of the SPSS program. Independent variables are images and objects. The dependent variable is accuracy. Independent T-test analysis [26] is carried out to calculate accuracy for both methods.

4. Tables and Figures

Table 121.1. Accuracy of both the groups Convolution Neural Network (CNN) and the Artificial Neural Network

Iterations	CNN Accuracy(%)	ANN Accuracy(%)
1	87.6	80.1
2	88.7	80.5
3	89.1	81.1
4	90.3	82.9
5	91.2	83.2

5. Results

The novel convolutional neural network (CNN) and artificial neural network (ANN) algorithms that were recommended were each put through their paces in Anaconda Navigator at different points in time. The sample size used was 10. The anticipated accuracy is shown.
Figure 121.1. Compare and contrast the CNN with the ANN. An algorithm for classifying data that is assessed according to its mean accuracy and loss. When compared to ANN's accuracy, CNN's overall precision is far higher. The CNN standard deviation is slightly more accurate than the ANN standard deviation when used as a classifier. On the X axis, we compare ANN Classifiers to CNN Classifiers, and on the Y axis, we compare the Mean Accuracy of Detection to +/-2 Standard Error.

Source: Author.

In Table 121.1, along with the loss that was brought about by the novel convolutional neural network (CNN). The anticipated accuracy is shown.

In Table 121.2, along with the loss that was brought about by ANN. In order to calculate numerical parameters that may be used for comparison, it is necessary to make use of these 10 data samples for each operation, in addition to the values that are specific to each loss. According to the results, may deduce that the novel convolutional neural network (CNN) had a mean accuracy of 91.8460%, while the artificial neural network (ANN) had a mean accuracy of 84.400%.

In Table 121.3 displays, on average, the degrees of accuracy that the novel Convolution Neural Network (CNN) and ANN have attained in their predictions. The standard deviation of the ANN's mean value is 3.43867, but the mean difference of the novel Convolutional Neural Network's (CNN) mean value is just 2.96015. This indicates that the ANN is less accurate than the novel CNN. The findings of an unsupervised sample T test that was done on novel convolutional neural networks (CNN) and an artificial neural network (ANN) are shown.

In Table 121.4, As can be seen in the table, the significant value that was discovered is 0.550 (p<0.05).

Figure 121.1, presents the findings of a comparison that was carried out between a novel convolutional neural network (CNN) and an artificial neural network (ANN) with regard to mean accuracy and loss.

Novel convolutional neural network (CNN) has a mean of 91.8460, a standard deviation of 2.96015, and a standard error mean of .93608. These numbers can

be seen in the table below. The means of the ANN, the confidence intervals of the mean, and the mean of the standard deviation are respectively 84.4000, 3.43867, and 1.08740. This is similar to the previous example. On the other hand, the mean amount of money lost by novel convolutional neural network (CNN) employees is 8.1540, the standard deviation is 2.96015, and the mean amount of standard error is.93608. These numbers may be found in the appropriate brackets down below. The following are the values for the mean loss, standard deviation, and mean standard error for ANN: 15.6000, 3.43867, and 1.08740, respectively.

In addition, there is a specification of the value for the group statistics, as well as the mean, the standard deviation, and the standard deviation mean for each of the two approaches. The graphical representation of the comparative research study, which categorizes the many ways in which the novel convolutional neural network (CNN) and ANN algorithms both come out on the losing end. This reveals that the novel convolutional neural network (CNN) is far more superior than artificial neural network (ANN), which obtained a classification accuracy of 84.400%, while the novel convolution neural network (CNN) has obtained a generalization ability of 91.8460%.

6. Discussion

According to the results of the aforementioned research, the significance value was found to be 0. The accuracy of novel convolutional neural networks has been determined to be 84. In a broad sense, the framework of a novel convolutional neural network can be broken down into two basic components: the anchor desk and the control room. The second section of the network consists of layers that are completely connected to one another, in addition to the classification layer. The novel Convolution Neural Network is now capable of learning characteristics at a wide range of sizes thanks to the way the network was created. The first layers of the novel convolutional neural network are required for the extraction of low-level characteristics like edges and corners, while the later layers of the novel convolutional neural network are essential for the extraction of higher-level features [11]. The experiments that are being conducted to assess whether or not the proposed novel Convolution Neural Network is successful in terms of reliability, precision, recall, and other metrics make use of the palm leaf manuscripts that have been collected and are written in cursive Tamil. According to the findings of the research, the proposed network was capable of successfully achieving an average accuracy of 94%. One of the disadvantages of this line of investigation is the fact that training a novel convolutional neural network requires

a considerable amount of time, which is especially problematic when dealing with very large datasets. The ultimate objective of this work lies in the future.

7. Conclusion

On the other hand, the accuracy value of the conventional artificial neural network (ANN) comes in at 84.400%, while the accuracy rate of the groundbreaking Convolution Neural Network (CNN) comes in at 91.8460%. According to the findings, the novel convolutional neural network (CNN) has a higher success rate of 91.8460 percent than the artificial neural network (ANN) does (84.4000 percent).

122 An efficient treatment for cherry tree disease using the random forest classifier comparison with the decision tree algorithm

Nandhini P.[1,a] and Mahaveerakannan R.[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai, India
[2]Project Guide, Department of Computer Science Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai, India

Abstract: The purpose of this research is to identify cherry plant diseases using the Novel Decision Tree and contrast the precision with the Random Forest Sorting device. Materials and Methods: For the most effective treatment of cherry tree disease, novel DT and random forests are employed with different training and testing splits. The study utilized sample sizes calculated with various novel DT and Random Forest training methods. For the treatment of cherry tree disease, testing splits are carried out using different training and testing divides, which enhances the security of poor accuracy. Using the GPower 0.80% program (with both the following configuration parameters: alpha = 0.05 and beta = 0.25). Result and Discussion: The novel decision tree worked well with a random forest classifier accuracy of 93.62% compared to a linear and radial basis function kernel accuracy of 92.78%, and independent sample T-tests were carried out on both methods. Hence the P value is less than 0.05, there is a statistically significant relationship between these two methods (P 0.05). Conclusion: In order to improve the accuracy of sharing machine learning data and storing sensitive information with therapy for cherry tree disease, According on the findings of this research, the Random Forest classifier algorithm appears to be fundamentally superior than the Novel Decision Tree. Testing splits are conducted using various training and testing splits to cure cherry tree disease, which increases the security of inaccurate results.

Keywords: Agriculture, cherry, novel decision tree, random forest classifier, security, treatment

1. Introduction

The may utilize a dataset that contains details about the symptoms of the disease and the appropriate therapies to assess the effectiveness of the RF algorithm in the treatment of cherry tree disease. Fungicide treatments and cultural techniques like pruning and removing affected wood can help stop the disease's spread [4, 14]. Environmental Impact: Infected cherry trees can spread the disease to other trees in the region, perhaps causing the loss of entire orchards or forested areas. Aesthetic Value: Irregularly shaped diseased cherry trees can detract from the beauty of parks, streets, and other urban settings. Ornamentals: Cherry trees are widely cultivated for their attractive flowers, which bloom in spring and are popular in parks, gardens, and streetscapes in Agriculture. Timber: Cherry wood is prized for its attractive grain, color, and durability, and is used in a variety of wood products, including furniture, flooring, and cabinetry [16]. Food and Beverage: Cherry juice, syrups, and other food and beverage products are made from the fruit and used in cooking and baking. These applications of cherry trees demonstrate their versatility and importance in many aspects of our lives. A survey of the literature on cherry trees would include information on a variety of subjects, such as their history, botany, horticulture, genetics, breeding, main illnesses, pests that harm them, and management

techniques. Both algorithms have their strengths and weaknesses, and the choice between them depends on the specific task and data. The study concludes that the Random Forest algorithm is fundamentally superior to Novel Decision Tree in enhancing overall precision for data exchange for machine learning and storing private information for cherry trees Security.

2. Materials and Methods

The completed Machine Learning Lab serves as the research location for the intended work, Department of Spatial Informatics, Saveetha Institute of Medical and Technical Sciences, Saveetha School of Engineering, and Saveetha Institute of Computer Science and Engineering (CSE). The Novel Decision Tree classifier is included within the first group, while the Random Forest is included in Group 2. By comparing the two controllers, the size of the sample has been calculated using Gpower software. The Gpower application has calculated the overall size of the sample by comparing the two units. Two categories were picked in the hopes of contrasting their methods and outcomes. 10 pairs of samples are selected out of each grouping for this investigation, totaling 10 samples [7]. Two techniques, the random forest classifier and innovative DT, are put into practice utilizing technological analytical techniques. The size of the sample is computed as 10 for every sample that used the GPower 0.80 program (Gpower setup parameters: alpha = 0.05 and beta = 0.25) with a significance level of p = 0.0384, where p is less than 0.05.

An open-access Kaggle dataset was utilized in this work [8,12]. With the use of this dataset, the training of random forests and decision trees using innovative algorithms to recognise these various stages will be made simpler. A customizable Jupyter notebook environment, a free GPU, and six hours of runtime are also provided, along with the ability for users to search for the datasets they want. The cherry plant dataset contains data on duplicate, null, and missing values for symptoms related to the cherry plant disease detection on agricultural security [15]. It has 105 rows and 10 columns. The cherry plant datasets have already been pre-processed to eliminate redundant and empty entries. Use the resources that Microsoft Excel offers. Translation of the data is not necessary because the dataset simply has numerical forms. Also enhanced are accuracy and security.

3. Novel Random Forest Algorithm

3.1. Description

One of the more popular contemporary machine learning techniques is the random forest classification (Novel RFC) Respect machines in machine learning look at the data used for regression and classification analyses using guided teaching methods and associated pedagogies. By explicitly translating the outputs towards high dimensionality regions, novel RFCs can efficiently perform nonlinear classification in addition to linear classification. The kernel function is the name of this tactic Security. It essentially draws lines between its classes. By maintaining a maximum range between both the percentage and the classes, the tolerances are drawn to reduce classifier mistakes while improving reliability and safety. "A Random Forest algorithm for classifying data is one that uses many decision trees, each of which is applied to a distinct portion of the overall dataset and uses the average to improve the predictive performance.

3.2. Pseudocode

Input

- Training dataset D
- Number of trees T
- Number of features F
- Maximum depth of each tree max_depth

Output:

- Random Forest model, consisting of T Decision Trees

```
for i in range (T):
    # Make a randomized selection from among the features that need to be considered for each tree.
    features_subset = randomly_select_features(D, F)
    # Make a sample of the data that is completely at random to utilize for this tree data_subset = randomly_select_data(D)
    # Train a decision tree on this data subset and features subset
    tree = train_decision_tree(data_subset, features_subset, max_depth)
    # Add the tree to the forest
    forest.add(tree)
    return forest
```

4. Novel Decision Tree Algorithm

4.1. Description

The Decision Tree Algorithm is a type of supervised machine learning approach that can be used for problems involving classification and regression. By recursively dividing the data into smaller groups based on the values of one of the input attributes, it creates a tree-like model of decisions and their potential effects. When it reaches a leaf node, which offers the predicted class or value, the algorithm applies the splitting rule based on the value of the related feature at each node. It has some benefits such as being simple to comprehend and interpret, quick and scalable, and resistant to minute fluctuations in the data. Unfortunately, it is

prone to overfitting and works with unbalanced datasets. In general, the algorithm known as the Decision Tree is powerful and widely used.

4.2. Pseudocode

Algorithm Name: Algorithm Based on a Decision Tree
Input:
The training program (S) with n examples, where each example has m attributes and a target attribute
List of attributes (A)
Output: Decision tree
Begin
Step 1: If all examples in Sreturn a leaf node with that value if they both have the same value for the target attribute.
Step 2: If A is empty, a leaf node should be returned with the value of the target property that is found in S the most frequently. This should be done even if S does not contain any values for A.
Step 3: Pick the most valuable quality (a) in order to split S based on the information gain criterion.
Step 4: Create a new decision node with attribute a.
Step 5: Partition S into subsets (S1, S2, ..., Sk) based on the possible values of attribute a.
Step 6: For each subset Si, create a new branch below the decision node and recursively apply the algorithm on Si using attributes A - {a}.
Step 7: Return the decision tree.
End

5. Statistical Analysis

For the purpose of carrying out the procedure of statistical analysis, the IBM is utilized as the SPSS tool. Random Forest belongs to Group 2, whereas the Novel Decision Tree classifier belongs to Group 1. Utilizing the SPSS software, creative decision Tree and Random Forest There is going to be an investigation into the statistical data. The abbreviation "SPSS" refers to the "Statistical Package for the Social Sciences." Tools measure performance by recall rate and f1 score. Compared to Novel DT, Random Forest performs somewhat better. Decibels are an independent variable, much like pictures, objects, distance, frequency, modulation, amplitude, and volume. If a test using an independent sample finds the time-fine-tuning decision Tree in order to achieve a competitive advantage that can be considered statistically significant over the Random Forest, the significance level is ($P < 0.05$). Symptoms, forecasting, quickness, security, and accuracy are among the dependent variables.

6. Tables and Figure

Table 122.1. Accuracy and Analysis of Random Forest and novel Decision Tree using 10 data sample size

Sample Size	novel DT Accuracy (%)	RFC Accuracy (%)
156	80.60	77.21
178	81.40	78.69
187	82.90	79.48
197	83.10	80.37
205	84.30	81.69
203	85.70	82.58
239	86.50	83.40

7. Results

The Decision Tree and Random Forest comparison for classifying cherry plant leaf disease attempts to increase disease identification precision. Random Forest is a deep learning technique, whereas RF is a more conventional machine learning strategy. Through the use of multiple evaluation measures like F-score = (2 * Precision * Recall) / (Precision + Recall), Recall = TruePositives / (TruePositives + FalseNegatives, Accuracy = (true positive + true negative)/(true positive+true negative+false positive+false negative), and Precision = TruePositives / (TruePositives + FalsePositives).

Figure 122.1 shows the difference between novels and Other Books in terms of the Mean Accuracy, Decision tree, and RFC. The graph shows that the Decision Tree is superior to the Random Forest when it comes to precision.

Table 122.3. Refers to the findings of an independent sample T-test that was carried out for two groups on the overall categorization accuracy value. The test was carried out on the overall categorization accuracy value. The conclusion that can be drawn from the fact that the P value is 0.038 less than 0.05 is that there is a difference that can be considered statistically significant between the two approaches

		Levene's test to determine whether or not the variances are equal		Using a T-test with a 95% confidence interval to evaluate whether or not the means are comparable is recommended.						
		f	Sig.	t	df	Sig. (2-tailed)	Mean difference	Std. Err or difference	Lower	Upper
Accuracy	Equal variances assumed	1.267	.275	.893	18	.038	–1.64800	1.84647	–5.52728	2.23128
	Equal Variances not assumed			.893	16.443	.038	–1.64800	1.84647	–5.55378	2.25778

Source: Author.

Table 122.4. Examining Random Forest and Decision Tree in terms of their respective degrees of precision in the novel

Classifier	Accuracy (%)
novel DT	93.62
RFC	88.78

Source: Author.

Table 122.1 shows both the level of precision that the RFC is expecting to achieve as well as the Novel DT's predicted accuracy. In order to compute statistical values that can be compared, each approach uses these 10 data samples in conjunction with the corresponding loss values. Following this, a table containing these values can be found below. The results show that the Novel DT's mean accuracy was 82.2020, while the RFC's mean accuracy was 87.8500.

Table 122.2 represents the Novel Decision Tree and RFC's average accuracy values. Novel DT's mean value is higher than RFC's, both having a standard deviation of 4.72154, but the latter having a standard deviation of 3.43533.

Table 122.3 T-test based on data collected from a separate sample results were carried out for two groups on overall classification of the accuracy value. The value of the P statistic is 0.038005, which indicates that there is a statistically significant difference between these two methods.

8. Discussion

Based on the findings of this research, it has been determined that the Novel Decision Tree classification method seems to be essentially superior to the Random Forest in how it improves the accuracy of sharing machine learning data, holding sensitive data with cherry plants, and security. The fungus Chondrostereum is the source of the fungal disease known as "Silver Leaf" on cherry
Figure 122.1. The contrast between novelDT and RFC, as shown. The mean value of a classifier's precision and loss. RFC has an accuracy that is, on average, lower than that of novelDT. Classifier: the standard deviation of novelDT is marginally superior to that of RFC. On the X axis is written "novelDT vs. Random Forest Classifier," while on the Y axis is written "mean detection accuracy with +/- 2 SD."

Source: Author.

trees. It can have an impact on the tree's wood as well as its leaves, causing the leaves to become silver or brown and the branches to wither [19]. Fungicide treatments and cultural techniques like pruning and removing affected wood in agriculture can assist in stopping the disease's spread. The necrotic centers typically generated shot holes and fell out using machine learning. Utilizing machine learning, and there is prior research that is in opposition to my idea, including cherry tree dataset bias in datasets. Detecting and managing cherry tree illnesses can be challenging due to various limitations. To improve cherry tree output and mitigate the impact of illnesses, it is crucial to develop more efficient systems for disease diagnosis and management. For instance, advancements in agriculture, artificial intelligence, and machine learning can facilitate the creation of more precise and effective approaches for detecting cherry tree diseases. Ongoing breeding efforts can also lead to the

development of cherry tree varieties that are less susceptible to illnesses, reducing the need for disease management and diagnosis. By overcoming the limitations in cherry tree disease detection and management, it is possible to enhance the overall resilience and productivity of cherry tree farming.

9. Conclusion

According to this study's findings, the special Decision Tree classifier algorithm appears to be in every essential respect superior than Random Forest in terms of giving an advantage to the security and precision of data stored in the cloud sharing and storage and performing personality quality checks on important content. According to this study, Decision Tree (mean = 82.2020) outperforms Random Forest (mean = 87.8500) with a significance level of 0.038. The accuracy rate of the novelDT is 93.62%. The accuracy of the new Decision Tree proportional technique is 93.62%, compared to 88.78% for the Random Forest method.

123 Detecting aquatic debris on ocean surfaces using AlexNet algorithm compared with the GoogleNet algorithm

T. M. Kamal[1] and N. Bharatha Devi[2,a]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Corresponding Author, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical And Technical Sciences, Saveetha University, Chennai, India

Abstract: This research delves into the comparison between the Novel Alexnet algorithm and the GoogleNet algorithm in their respective abilities to detect and classify aquatic debris on ocean surfaces. The dataset comprises 324 JPG file format photographs of aquatic debris and 724 JPG file format images of the clear ocean, including noise-filled images. Novel AlexNet algorithm is compared with GoogleNet algorithm in detecting the aquatic debris considering each group iteration as 20 where G-power is 80% and 95% confidence level. Upon completion of the research, the Novel AlexNet algorithm exhibited a remarkable accuracy of 93.77%, surpassing the GoogleNet algorithm, which achieved an accuracy of 92.40%. These findings highlight a statistically significant distinction in the performance of the two algorithms for detecting aquatic debris on ocean surfaces, with a p-value of 0.011 obtained from an Independent Sample T-test ($p < 0.05$). In the domain of forecasting aquatic debris, the Novel AlexNet method shines in terms of accuracy, surpassing the GoogleNet algorithm, as indicated by the findings.

Keywords: Novel AlexNet algorithm, convolutional neural network, deep learning, GoogleNet algorithm, marine debris, ocean surfaces, water

1. Introduction

One of the main reasons for the hostile maritime environment, which has attracted increasing attention from all around the world, is marine garbage. The bulk of rubbish has in fact been washed into the water and eventually sinks to the bottom of the deep ocean as a result of increased human influence on the shore and ocean [1]. Deep-sea debris will represent larger damage to the marine ecosystem and organism survival than garbage on the ocean's surface [2]. The significance of microplastics lies in their minute dimensions, the inherent challenges in accurately measuring the abundance of the smallest microplastics in the environment using current technology, and the looming concerns over their potential harm to both human populations and marine ecosystems [3]. The advent

of Novel AlexNet heralded a swift transformation in the landscape of deep learning for object recognition and detection. Following this breakthrough, a cadre of researchers stepped forward to harness the power of deep learning in the domain of underwater image recognition, and over time, this technique underwent a steady process of refinement and growth [4]. Deep Learning methods and their applications may be used to automate the removal of marine garbage, identify its distribution, and boost the process' efficiency by improving debris identification.

Over the last four years, IEEE Xplore has seen the publication of 81 papers, while Google Scholar boasts a staggering 2250 relevant entries. In the realm of deep learning, the integration of temporal and contextual data into object detection has proven instrumental in implementing detection strategies when analyzing

debris images [5]. Remote sensing images exhibit an exponential surge in information as the spatial resolution escalates, and the accelerating processing capabilities of computers, as exemplified by [6] have empowered the field. The advent of Novel AlexNet has played a pivotal role in addressing this challenge, and the concept of Weakly Supervised Learning further streamlines the process by necessitating only image-level annotations denoting the presence or absence of target objects. This research uses the Novel AlexNet algorithm to classify objects and utilizes the backbone network [7]. A noteworthy drawback in this research is the alteration of the architecture, which involves replacing the final two fully connected layers with a Global Average Pooling layer and two convolutional layers. In contrast, the paper being compared utilizes a more elaborate design with five convolutional layers and a network comprising eight interconnected layers. Object detection using GoogleNet was a promising approach that helps for the compared proposal research since GoogleNet solved majorly network faced problems via Inception module utilization [8]. Incorporating the inception module into a neural network design allows for the exploitation of feature detection across various scales via convolutions employing distinct filters, while concurrently optimizing the training process by reducing computational overhead through dimensionality reduction [10].

The current system's limitations, notably its poor accuracy, have prompted the recognition of a research gap. One of the critical drawbacks of the existing system is its heavy reliance on extensive datasets to predict accuracy. In contrast, the Novel AlexNet algorithm, proposed in this study, operates with a leaner dataset requirement for training and testing, while delivering superior accuracy. The primary objective of this research is to compare the performance of the Novel AlexNet algorithm against the GoogleNet algorithm in the context of detecting aquatic debris on ocean surfaces.

2. Materials and Methods

The research conducted in this study took place at the image processing laboratory within the precincts of Saveetha School of Engineering, which is affiliated with the Saveetha Institute of Medical and Technical Sciences. In each experimental group, precisely 20 samples were meticulously chosen, following the methodology documented by [11] in their study. This research harnesses the power of two distinct algorithms, namely Novel AlexNet and GoogleNet. The sample size for computation was determined by applying an 80% G-power value, an alpha level of 0.05, and a beta value of 0.2, all encompassed within a 95%

confidence interval. Additional details are available at (https://clincalc.com/stats/samplesize.aspx)

The proposed work was developed and executed using the MATLAB software, with Kaggle providing the dataset for the code implementation. The dataset consists of 724 JPG file format images depicting clear ocean and 324 JPG file format images depicting aquatic debris, enabling the identification and analysis of both clear ocean and debris records [13]. For the hardware setup, an Intel Core i3 processor with a minimum of 4 GB RAM was employed, operating on a 64-bit system architecture. The code implementation was facilitated using MATLAB, and the accuracy of the code's execution was bolstered by incorporating an image dataset.

2.1. Novel AlexNet algorithm

Novel AlexNet Algorithm is used as a sample preparation of group 1. The novel AlexNet technique uses eight layers, consisting of five convolutional layers and three linked layers, to compensate for its shortcomings. Each layer contains convolutional filters and the non-linear activation function ReLU. The use of Rectified Linear Units (ReLU) in Novel AlexNet enables models to learn and resolve issues more efficiently while eliminating gradient difficulties [11]. Novel AlexNet was the first convolutional network to enhance GPU performance, achieving remarkable results on a challenging dataset with only supervised learning. Its success in CNN has ushered in a new era of research. Implementing Novel AlexNet is relatively straightforward since several deep learning frameworks are available.

Pseudocode
Input—Dataset records
1. Eliminate background noise from object images through pre-processing.
2. Utilize the threshold algorithm to convert the pre-processed image into a binary image.
3. The binary image's components must be identified.
4. Segment all of the elements that are present in the image.
5. For each item, extract the central axis, minor axis, and area geometric characteristics.
6. Utilize the average feature values retrieved to evaluate the sample's quality.
7. Sort the selection into groups based on examining its kind and grade.

2.2. GoogleNet algorithm

GoogleNet algorithm is used as a sample preparation of Group 2. The advent of GoogleNet marked a significant milestone in addressing the issues inherent in massive neural networks, primarily attributed to its

incorporation of the Inception module. This specialized neural network architecture strategically utilizes dimensionality reduction to optimize the computational efficiency of training extensive networks, all the while achieving multi-scale feature detection through a variety of convolutional filters. The GoogleNet Architecture has a total of 22 levels and 27 pooling layers. There are a total of 9 linearly stacked inception components. A machine learning distributed system with moderate model and data parallelism is used to train GoogleNet [12]. The inception module is constructed using several minor convolutions. Object detection, quantization, and object identification are some of the key applications.

Pseudocode
Input—Training Set

1. Begin by loading the pre-trained GoogleNet model, and proceed to create a novel model structure. This new architecture includes the addition of a global average pooling layer followed by a fully connected layer employing sigmoid activation, tailored specifically for binary classification.
2. Compile the new model using an optimizer, loss function, and evaluation metrics.
3. Augment the training data using the ImageData-Generator function to reduce overfitting.
4. Train the new model using the fit_generator method and evaluate it on the validation set using the evaluate_generator method.
5. Fine-tune the GoogleNet model by unfreezing some of its layers and retraining on the augmented data with a smaller learning rate. Use the trained model to predict the presence of aquatic debris in ocean surface images.

2.3. *Statistical analysis*

Statistical analysis of the Novel AlexNet and GoogleNet algorithms is conducted using SPSS software. In this analysis, the dependent variables encompass a range of characteristics, such as images, objects, distance, frequency, modulation, and pixel distribution. Concurrently, the independent variables under scrutiny include frame rate and resolution. The statistical software used was IBM SPSS version 26. For both Novel AlexNet algorithm and GoogleNet, sample sizes of 10 were used to create a dataset. Accuracy and loss are the testing variables, grouping is done using the Group ID.

3. Results

A novel AlexNet algorithm is used efficiently to predict aquatic debris in ocean surfaces, and its accuracy is 93.77% compared to that of the GoogleNet algorithm with accuracy of 92.40%. Table 123.1 displays the mean and accuracy values for both AlexNet and GoogleNet. In comparison to GoogleNet, which exhibits standard deviations of 1.63330 and 1.32492, respectively, the mean value of AlexNet surpasses its counterpart. The mean for the existing algorithm is 92.40% and that of the proposed algorithm is 93.77. These values give an overview of the central tendency and variability of the data for each group.

In Table 123.2, the independent sample T-test results for AlexNet and GoogleNet highlight a noteworthy finding: there exists a statistically significant distinction between the Novel AlexNet Algorithm and GoogleNet Algorithm ($p = 0.011$, with $p < 0.05$).

Figure 123.1 illustrates the comparative analysis of mean accuracy and loss between AlexNet and GoogleNet. The T-test results for the AlexNet and ResNet algorithms are visually depicted as bar graphs, providing a clear representation of accuracy and loss values for both AlexNet and GoogleNet.

4. Discussion

Based on the results of the independent sample T-Test, this study revealed a significance value of 0.011 ($p < 0.05$), indicating a statistically significant difference between the two groups. Moreover, the accuracy assessment demonstrated that the Novel AlexNet classifier achieved a high accuracy rate of 93.77%, surpassing the GoogleNet classifier, which achieved an accuracy of 92.40%.

Comparative previous study assessment of GoogleNet achieves an accuracy of 92.40The results

Table 123.1. Demonstrates the group statistical analysis for the proposed ALEXNET and the comparison algorithm GOOGLENET. It includes the mean, standard deviation, and standard error mean for a sample size of 20 per group

Group		N	Mean	Std. Deviation	Std. Error Mean
Accuracy	AlexNet	20	93.7730	1.6330	0.36522
	GoogleNet	20	92.4080	1.32492	0.29626

Table 123.2. Demonstrates the results of an independent samples T-test that was conducted to compare the proposed ALEXNET with the existing algorithm GOOGLENET. The significance among the groups shows p=0.011 (p<0.05) and results statistically significant

		Leven's Test of Equality of Variances		T-test for Equality of Means					95% Confidence Interval of the Difference	
		F	Sig	t	df	Sig (2-tailed)	Mean Difference	Std Error difference	Lower	Upper
Accuracy	Equal Variance assumed	5.760	0.021	2.664	38	.011	1.25300	0.47027	.30099	2.20501
	Equal Variance not assumed			2.664	36.449	.011	1.25300	0.47027	.29966	2.20634
Loss	Equal Variance assumed	1.854	0.181	-.551	38	.585	-.28250	0.51276	-1.32052	-.75552
	Equal Variance, not assumed			-.551	37.919	.585	-.28250	0.51276	-1.32060	-.75560

Source: Author.

suggest that the Novel AlexNet approach outperforms GoogleNet as a classifier, with an accuracy rate of 93.77% for Novel AlexNet compared to 92.40% for GoogleNet. This study presents a comparative accuracy analysis between the two models, highlighting the superior performance of Novel AlexNet. Eight layers are used in the Novel AlexNet technique to categorize objects and extract those that are present in the picture [7]. This research application can be used in classifying the Debris on Ocean surfaces and shores. Few other applications include the help of this approach [17] the amount of garbage that is mixed with water bodies is determined. To properly categorize an input pattern as one of the several output classes is the primary objective of image recognition. The two key phases of this technique are feature selection and categorization (Wang 2022). Feature selection is crucial to the entire process since the classifier won't be able to discriminate between characteristics that are improperly chosen.

The gathering of datasets from different sources is one of the aspects influencing the study. The time needed to categorize the data for both detection and classification has an impact on the study as well. The limitation of this study, the debris present below the surface cannot be determined due to the lack of light below the surface. In terms of future prospects, this study paves the way for expanding the system's capabilities by incorporating a more extensive array of objects while concurrently reducing the time required for data set training.
Figure 123.1. The bar graph represents the comparison of mean for the proposed ALEXNET algorithm with the existing GOOGLENET algorithm. X axis represents ALEXNET Vs GOOGLENET and Y axis represents mean and Error Bars 95% CI, +/-2 SD.

Source: Author.

5. Conclusion

To enhance image classification accuracy, this study leveraged the Aquatic Debris Recognition Data set. A performance comparison between the Novel AlexNet and GoogleNet algorithms revealed that Novel AlexNet outperformed GoogleNet, with a mean accuracy of 93.77% for the former compared to 92.40% for the latter. Consequently, Novel AlexNet demonstrated superior accuracy over GoogleNet.

124 Determining the accuracy in examining the human lifespan by using Novel K-Nearest neighbor algorithm comparing with RIPPER algorithm

S. Tejasree[a] and A. Shri Vindhya

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The purpose of this research is to evaluate Novel KNN and the RIPPER algorithm in terms of their ability to accurately predict a person's lifetime. Materials and Methods: There are a number of ways that the novel KNN method and the RIPPER algorithm may be emulated. In this study, 10 samples are utilized for each method, with the sample size being computed using G power 80% for two groups. Results and Analysis: Discussion and Analysis evidence suggests that the Novel KNN method outperforms the RIPPER algorithm by a wide margin (85.1400% vs. 77.5000%). Two groups were statistically significant at the $p=0.006$ level of significance ($p<0.05$). Conclusion: When comparing lifespans, the novel KNN method outperforms the RIPPER algorithm.

Keywords: Novel K-Nearest neighbor algorithm, RIPPER algorithm, financial inclusion, accuracy, lifespan, machine learning

1. Introduction

The typical number of years an individual may be expected to live is known as their "Time of Presence." It tends to be finished for a scope of ages and assumes that age-specific death rates will remain stable [4]. A country's mortality rate is summarized by this statistic, which allows us to compare rates over generations and spot patterns and financial inclusion [12,15]. Its understanding and importance are extensively more nuanced and may inform us of an incredible arrangement regarding a country's government assistance state's degree of development and financial inclusion. My goal in selecting and highlighting this issue is to develop a system [6] that, utilizing a number of different machine learning methods, can estimate how long a person may be expected to live [11]. The seven classifiers were tested on two datasets using machine learning techniques such as simple linear regression, KNN, Decision tree and Random Forest, C4.5 classifier, One Rule, and Support vector machine. The applications of this approach helps in the monetary consideration including extra security, annuity arranging, financial inclusion and improvement of individuals government assistance by the public authority [9].

Predicting lifespan research yielded around 4,320,000 articles in IEEE Xplore and 24,5620,000 papers in Google Scholar [2,5,18]. As a result, we anticipate that the results of this study will serve as a guide for governments throughout the world to invest more resources into improving the health of their citizens and their financial inclusion, thus extending the average lifespan [16]. When a region or nation has a short life expectancy, it's crucial to implement social programmes that improve not just health but also environmental quality, access to financial inclusion, food security, and dietary needs [8].

The expertise and experience of the team members in the field of research has resulted in several high-quality publications. There is a downside to this study in that it may lead to more cases of sickness, disability, and dementia as well as the aging issue [1,9]. The United Nations Population Division assesses that by 2050, the worldwide populace of grown-ups aged

60 or more will have dramatically increased from its ongoing degree of 800 million (11% of the total) (22 percent). In other words, by 2050, the elderly will constitute over 25% of the global population [7]. Twenty or thirty percent of a country's population being over 65 is a reality in a society with low fertility, low mortality, and limited immigration. There are several issues that arise as a result of a population that is becoming older.

This research goal is to evaluate Novel KNN accuracy in making lifespan predictions in comparison to that of RIPPER.

2. Materials and Methods

The study reported here was conducted at the Cyber Forensic Laboratory at the Saveetha School of Engineering at SIMATS (Saveetha Institute of Medical and Technical Sciences). There were two teams suggested for the anticipated role. The KNN strategy is addressed by Gathering 1, though the RIPPER procedure is displayed in Gathering 2. Both the K-Nearest Neighbor calculation and the RIPPER calculation were exposed thorough testing, with G power set at 80%, an sample size of 155, a certainty time period, and a pretest force of 80%, all with a most extreme allowed blunder of 0.05 [19].

After the datasets were collected from Kaggle (Human_life_Expectancy.csv) [10], they were preprocessed and cleaned to get rid of unnecessary or irrelevant information. Data correctness is determined by the Novel KNN and RIPPER algorithms, which are implemented in the prediction model after it has been cleaned and preprocessed using the OpenCV library.

Devices that meet the requirements of a certain hardware configuration are referred to as "hardware configuration devices," and they are assigned a unique set of parameters and computing resources. The following components: CPU: Intel Core i3, Memory: 4GB, Hard Drive Capacity: 500GB.

In order for the programme to run correctly, there are certain hardware components that must be present on the end device, and these are what are referred to as "software requirements." This model requires at least Windows 7/8/10, Python 3, and the integrated development environments (IDEs) PyCharm and Google Collab.

2.1. K-nearest neighbor algorithm

With regards to regulated learning, KNN is one of the easiest AI calculations. KNN utilizes a presumption of closeness between the new case/information and existing cases to allocate it to the classification that best matches the current classes [7]. The KNN method is frequently utilized for characterization issues, but it may also be utilized for Regression. The KNN algorithm

remembers all the information it has, and then uses that information to decide how to order another data of interest. This infers that the KNN calculation might be utilized to rapidly and precisely sort new information into the most suitable class. Table 124.5 represents the pseudocode of the KNN algorithm.

2.2. RIPPER algorithm

Rule-based categorization is the basis of the RIPPER algorithm. Reiterative incremental pruning for error minimization is what it means. From the data used for training, it creates a set of rules. This rule induction method is frequently implemented. It excels on datasets when the distribution of classes is uneven. If most of the entries in a dataset are from one class while the others are from other classes, it means that the dataset has an uneven distribution of class [13]. In order to avoid model overfitting, it employs a validation set, making it suitable for usage with noisy datasets. Table 124.6 represents the pseudocode of RIPPER algorithm.

2.3. Statistical analysis

Using SPSS software, novel KNN and RIPPER algorithm-based techniques are statistically examined. The independent variables are age, character, mannerism

Table 124.1. Dataset name, extension and source

Table 124.5. Pseudocode for Novel KNN algorithm

Step 1: Collect the data you wish to use for building the KNN model.
Step 2: Pre-process data this involves cleaning the data, handling missing values, and removing irrelevant features.
Step 3: Choose a value for k, which represents the number of neighbors to consider when making a prediction.
Step 4: Calculate the distance between the new data point and all the other data points in the training dataset using a distance metric such as Euclidean distance.
Step 5: Select the k data points with the shortest distance to the new data point.
Step 6: Predict the class or value for classification tasks, assign the most common class among the KNN as the predicted class for the new data point. For regression tasks, take the average value of the KNN as the predicted value for the new data point.
Step 7: Evaluate the performance of the KNN model on a test dataset.
Step 8: Tune the value of k and adjust the value of k to optimize the performance of the model.

Source: Author.

Table 124.6. Pseudocode for RIPPER algorithm

Step 1: To use a 'separate and conquer' method to add conditions to a rule until it perfectly classifies as a subset of data.
Step 2: Just like decision trees, the information gain criterion is used to identify the next splitting attribute.
Step 3: When increasing a rule's specificity no longer reduces entropy, the rule is immediately pruned.
Step 4: Until reaching stopping criterion step one and two are repeated at which point the whole set of rules is optimized using a variety of heuristics.
Step 5: Obtain results.

and the dependent variable is disease. KNN accuracy is calculated using independent sample T test analysis for both methods [1].

3. Results

Table 124.1 shows the data set for different contexts and regions. Table 124.2 shows the simulation results of the proposed KNN strategy and the RIPPER calculation, with a sample size of 10. KNN had an average accuracy of 85.1400%, while RIPPER had only 77.5000%. Table 124.3 shows a T-test

GRAPH

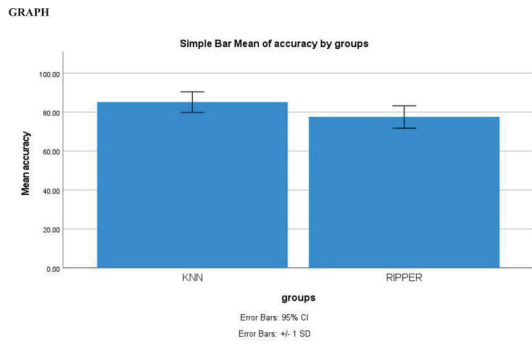
Simple Bar Mean of accuracy by groups


Figure 124.2. KNN has a mean accuracy of 85.1400%, whereas the current RIPPER algorithm only manages 77.500%. KNN has better average accuracy than the RIPPER algorithm. KNN against RIPPER along the X axis. Accuracy means on the Y axis. The margin of error is +/- one standard deviation.

Source: Author.

comparison of the KNN and RIPPER algorithms. A T test was performed on each independent variable to decide the mean, standard deviation, and standard bungle of the mean in order to compare the groups. The KNN method outperforms the RIPPER algorithm. The results of a thorough analysis using the T-test are shown in Table 124.4; the conclusion, if the p-value is less than 0.05, then the difference between the groups is statistically significant.

The pseudocode for the KNN algorithm is shown in Table 124.5. The pseudocode for the RIPPER algorithm, which is an ensemble learning technique for both relapse and order issues, is shown in Table 124.6. The architecture diagram of the KNN and RIPPER algorithms is shown in Figure 124.1. According to Figure 124.2, the mean accuracy of the KNN method is 85.1400%, while the current RIPPER technique has a value of 77.5000%. The KNN method outperforms RIPPER in terms of average accuracy. In terms of accuracy, KNN is on the X-axis, while RIPPER is on the Y-axis. The error margin is +/-1 standard deviations.

4. Discussion

Both the Novel KNN and RIPPER algorithms were used in this study. In order to forecast Period of Existence precision and evaluate it against the RIPPER method. The KNN calculation has a higher mean exactness (85.1400%) than the RIPPER method (77.5000%) does.

Algorithms such as KNN, ONE RULE, Support Vector Machine, C4.5 Classifier, and RIPPER are used in the study. Compared to the innovative KNN, whose accuracy is 0.85, RIPPER is shown to have the lowest accuracy, at 0.77 [4]. The KNN performs better

than the RIPPER method, as shown by a comparison with that algorithm. KNN is 85.1400% accurate, but RIPPER is only 77.5000% accurate in the book. The architecture found in Figure 124.1 represents the process of predicting the period of existence using data preprocessing, collection of dataset, data selection and testing the data and obtaining the results. Any action taken on raw data in order to get it ready for further processing is considered data preparation. The information for the processing is gathered in a dataset. The phrase "data selection" refers to the process of deciding what kind of data is needed, where to get that data, and what tools will be most useful in gathering that data. Testing the data is to satisfy the execution preconditions and input content required to obtain the results. Similar, conclusive findings have been obtained [19]. They also tested unsupervised machine learning algorithms for financial inclusion, finding that the innovative KNN approach outperformed the others with the best accuracy. Four of the works had consistent conclusions with the study, while the fifth had opposite results [5]. Furthermore, the unique KNN algorithm seems to have greater accuracy and performance in all scenarios than the RIPPER method, as shown by the preceding talks and conclusions.

Gender, genetics, healthcare availability, environmental factors, diet, physical activity, and other lifestyle factors, financial inclusion and even safety conditions in the community all have a part in how long a person lives. According to the available data, there are two primary determinants of lifespan: genes and lifestyle [3,13,14,17].

The few limitations are computationally expensive and overfitting. It is possible that in the future, this model will also be utilized to maximize data accuracy and to better investigate lifespan. Classifiers computation time may be reduced and their diagnostic accuracy can be improved by using quality choice algorithms in the future.

5. Conclusion

The Novel KNN method seems to have improved accuracy of (85.1400%) when predicting the era of existence compared to the RIPPER algorithm (77.5000%) in this study. All of the data points to the government's efforts to increase people's financial security by providing them with things like life insurance and retirement plans.

Abstract: The objective of this study is to enhance the precision of sales forecasting in major supermarkets through a comparative examination of XG Boost and Gradient Boosting techniques. Materials and Methods: For estimating sales at large supermarkets, Novel XG Boosting and Gradient Boosting are used with variable training and testing splits. The total data set used in this research is 13,930 observations in which 11,144 observations used for training and 2786 observations used for testing. The Gpower test employed has an approximate power of 85% with the G power settings specified as $\alpha=0.05$ and power=0.85. Result: The accuracy of Novel XG Boosting (92.7100%) was found to be significantly higher than Gradient Boosting (87.7500%) with a p-value of 0.02 ($p<0.05$), Suggesting a statistically significant disparity between the two algorithms. for predicting sales at large supermarkets. These results suggest that Novel XG Boosting is a better performing algorithm than Gradient Boosting. Specifically, the accuracy analysis of Novel XG Boosting was found to be 92.7100%, while the accuracy of Gradient Boosting was 87.7500%. Conclusion: When compared to Gradient Boosting, Novel XG Boosting has a higher accuracy for predicting sales at large supermarkets.

Keywords: Novel XG boosting, gradient boosting, sales, super markets, forecast, regression, machine learning

1. Introduction

The research has been carried out on Analysis of the performance for predicting sales at large supermarkets; an average of 106 research papers have been published, with 35 appearing on Science Direct and an additional 35 on IEEE Xplore. This study compares the effectiveness of three different approaches to the problem of predicting Walmart sales: the classic time series model, a hybrid approach that combines elements of the time series model and a machine learning model, as well as a purely machine learning approach. The main use of performance analysis for estimating sales at large supermarkets is measuring the accuracy of predicting future demand for products and inventory availability levels, which has been critical, particularly in grocery shops or supermarkets. The purpose is to forecast sales for supermarkets using several regression and boosting techniques and determining which approach is most suited to the problem at hand. When compared to any of the widely recognized single-model predictive learning algorithms, the two-level method utilized in this study to estimate product sales from a given outlet produces better predictive performance [9]. The XGBoost sale prediction model is proposed in this research to solve Walmart's sales forecast challenge by combining the XGBoost algorithm with careful feature engineering processing. The approach presented in this paper is versatile enough to mine properties across multiple dimensions, allowing for accurate prediction. In this essay, they suggest a methodology for predicting Walmart sales using a neural network. The objective of this study is to enhance classification accuracy through the introduction of a novel XG Boosting approach and evaluating its performance against Gradient Boosting. The suggested methodology enhances performance analysis for predicting sales at major supermarkets.

2. Materials and Methods

The investigation took place in the User Interface Design Lab within the Cloud Computing department at Saveetha School of Engineering. The determination of the sample size utilized GPower 3. This study uses sales data from large supermarkets to compare the performance of XGBoost and Gradient Boosting techniques for sales prediction. The data analysis phase involves preprocessing the data to ensure that the features used in the models are relevant to the task of sales prediction. Feature engineering techniques such as one-hot encoding, normalization, and feature scaling are used to prepare the data. XGBoost and Gradient Boosting models undergo training using a subset of the data and subsequent evaluation on a separate holdout set. Next, may utilize the features of the new data to make predictions about which group a record should be placed in. When the linear separation of the data is simple, a linear kernel function is advised. The study involves two identified groups, each with a sample size of N=10, as referenced in. The dataset used in the study was obtained from Kaggle.com.

2.1. XGBoost

Extreme Gradient Boosting (XGBoost) is a scalable machine learning system based on gradient-boosted decision trees (GBDT). It excels as the premier machine learning toolkit for tackling regression, classification, and ranking tasks, complete with parallel tree boosting capabilities. It includes tree learning methods as well as linear model solvers. As a result, its capacity to execute parallel processing on a single computer is what allows it to be fast. The following are the steps of XGBoost.

Step 1: Input the dataset and relevant parameters

Step 2: Generate an initial prediction and assess residuals by computing the discrepancies between the predicted values and the ground truth values.

Step 3: Build an XGBoost tree model and then prune it to avoid overfitting.

Step 4: Calculate the output values for each leaf in the pruned tree using the residuals as the target variable.

Step 5: Generate new predictions by summing up the preliminary prediction and the output values of the corresponding leaf in the pruned tree.

Step 6: Make residual calculations using the new predictions by subtracting the actual values from the new predictions to obtain the new residuals.

Step 7: Repeat steps 3 to 6 for a specified number of trees or until the residuals converge to a minimum level. Output the final model and relevant performance metrics.

2.2. Gradient boosting

A machine learning technique known as gradient boosting is employed in tasks such as regression and classification, among other applications. It produces a prediction model represented as an ensemble of weak prediction models, typically decision trees. To address classification and regression issues, gradient boosting is used. The model's performance becomes better with each iteration in this sequential ensemble learning technique. This process builds the model in a stage-by-stage manner. The following are the steps of the Gradient Boosting.

Step 1: Input the dataset and relevant parameters

Step 2: Define the initial parameter values, such as the maximum depth of the tree, minimum samples per leaf, and splitting criteria.

Step 3: Calculate the mean of the target value for the entire dataset as the initial prediction.

Step 4: Calculate the residuals for each sample by subtracting the predicted value from the actual value.

Step 5: Build a decision tree using the residuals as the target variable and the other features as the predictors.

Step 6: Make predictions by adding the initial prediction to the output of the decision tree.

Step 7: Assess the results through the computation of performance metrics like mean squared error, mean absolute error, or R squared.

Step 8: Repeat steps 4 to 7 for a specified number of iterations or until the performance metrics reach a minimum threshold. Output the final model and relevant performance metrics.

2.3. Statistical analysis

In the statistical assessment of Novel XG Boosting as well as Gradient Boosting [9], utilized SPSS software. The independent factors in the analysis encompass image, objects, distance, frequency, modulation, amplitude, volume, and decibels. The dependent variables consist of images and objects. To gauge the accuracy of both approaches, an independent T-test analysis is conducted.

3. Results

The recommended Novel XG Boosting and Gradient Boosting models were executed in Anaconda Navigator at various intervals, each with a sample size of 10. The projected accuracy of Novel XG Boosting is presented in Table 125.1, while Gradient Boosting's anticipated accuracy is displayed in Table 125.2. Based on the results, Novel XG Boosting achieved a mean accuracy of 92. 7100%, whereas Gradient Boosting achieved a mean accuracy of 87. Notably, the mean accuracy of Novel XG Boosting surpasses that of Gradient Boosting, with corresponding standard deviations of a12 and a22. Table 125.4 presents the results of the Independent sample T-test for Novel XG Boosting and Gradient Boosting, revealing a significance value of 0. Additionally, Figure 125.1 provides a visual representation of the mean accuracy comparison

between Novel XG Boosting and Gradient Boosting. For Novel XG Boosting, the mean, standard deviation, and standard error mean are denoted as a11, a12, and a13, respectively. The comparative analysis of loss between Novel XG Boosting and Gradient Boosting is illustrated graphically, highlighting the distinctions between the two approaches. 7100% accuracy than Gradient Boosting with 87.

4. Discussion

The obtained significance value in this study is 0. 02, suggesting that Novel XG Boosting outperforms Gradient Boosting. The accuracy analysis indicates that Novel XG Boosting achieves an accuracy of 92. This research introduces a novel computational intelligence framework for rapidly learning review ratings in the e-commerce domain. The findings suggest that for one-year-ahead projections, equity ratio, liquidity ratio, and debt-to-sales ratio are the most relevant indicators of tax defaults. 0 software, revealing that the factors influencing continued intention to use ABC Access, ranked from highest to lowest, are Hedonic Motivation, System Quality, Habit, and Performance Expectancy. The model, with an R-squared value of 72%, demonstrates strong predictive capabilities for
Figure 125.1. A comparison between XG and Gradient Boosting. Classifier in terms of mean accuracy. Gradient Boosting has a lower mean accuracy than Novel XG Boosting. users' intent to continue using ABC Access. By increasing the order of the underlying dynamical system, the Hankel block enables the estimation of hidden oscillatory modes. The proposed technique was evaluated in a case study involving the long-term prediction of weekly sales for a chain of retailers. The future scope of this study includes expanding the system to incorporate a larger number of objects while reducing the time required for training the dataset.

5. Conclusion

An accuracy of Novel XG Boosting is measured at 92.7100%, while Gradient Boosting achieves an accuracy of 87.7500%. Based on the analysis, Novel XG Boosting (92.7100%) demonstrates superior performance compared to Gradient Boosting (87.7500%). This research conducts a comparative evaluation of XGBoost and Gradient Boosting techniques for sales prediction in large supermarkets using machine learning and data analysis. The findings indicate that both models achieve high levels of accuracy, precision, recall, and F1-score for sales prediction. However, the XGBoost model surpasses the Gradient Boosting model in terms of predictive capability and processing speed. This study underscores the significance of feature engineering and hyperparameter tuning in attaining optimal model performance. The outcomes of this research hold practical implications for supermarkets and retailers, providing insights for optimizing inventory management, staffing, and marketing strategies. The study also provides a foundation for further research in sales prediction using advanced machine learning techniques. Overall, the comparative analysis of XGBoost and Gradient Boosting models conducted in this study can help inform decisions related to sales forecasting in the retail industry.

126 Analysis of a recurrent time delay neural network and Gaussian Naive-Bayes algorithms for effective flood prediction techniques using accuracy

D. Anjireddy[1,a] and K. Jaisharma[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Research Guide, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: This study aims to assess the accuracy of flood forecasting in India using a Novel Recurrent Time Delay Neural Network (NRTDNN) and to benchmark it against Gaussian Naive-Bayes (GNB) for performance. Materials and Methods: The research work consists of 2 Sample groups in which group 1 NRTDNN consists of 20 sample sizes and group 2 GNB consists of 20 sample sizes. The Clinical website used to perform the calculation with the set G-power to 0.80, alpha to 0.05, beta to 0.95 and use a 95% confidence interval. Results: After performing all the analysis in the research the Novel Recurrent Time Delay Neural Networks Algorithm has produced 91.40% accuracy and the Guassian Naive-Bayes has produced 86.41% accuracy. Along with implementation conducted an independent sample T-Test to compare the means of two groups. The result showed a p-value of 0.000, which is lower than the significance level of 0.05, that states there is a statistically significant difference between the groups. Conclusion: The accuracy in flood prediction using the NRTDNN appears and climate change to have a higher prediction accuracy percentage (91.40%) than the GNB algorithm (86.41%). The accuracy in the existing research is improved by the proposed research of NRTDNN which produces better accuracy than the GNB algorithm to improve flood prediction accurately.

Keywords: Gaussian Naïve-Bayes, machine learning, climate change, flood forecasting, flood prediction, novel recurrent time delay neural network

1. Introduction

The research is about India's flood prediction using computers programmed with Machine Language models and analyzes the improvement of accurate prediction in comparison. In recent years, the primary use of Machine Learning techniques has been to improve the efficiency and reduce the costs of advanced prediction systems and climate change [6]. A number of research papers on the existing system have been published between 2018 and 2022 in the IEEE Explore and Science Direct databases, as shown by the literature review. This paper proposes the use of a NRTDNN approach for flood prediction. In this paper, accuracy of flood prediction was significantly enhanced by the proposed algorithm, achieving 92% with NRTDNN and 85% with GNB algorithms. The paper also proposes a novel application of neural networks for flood prediction, which resulted in an accuracy value of 91%. In this paper, the authors present a technique for improving the accuracy of flood prediction through the use of machine learning algorithms. According to the results, the prediction accuracy of the existing algorithm was 85. This research proposal aims to improve the readability and accuracy of flood prediction through the comparison of these two algorithms. Also, the comparison between the NRTDNN and the GNB in order to determine which provides accuracy rate for flood prediction.

2. Materials and Methods

The conducted experiment took place in the Computer Science Engineering Lab, located at the Saveetha School of Engineering within the Saveetha Institute of Medical and Technical Sciences. The study will involve Group 1, which will use the NRTDNN and Group 2, which will use the GNB. Each group will consist of 20 samples. To perform the research comparison, the sample size calculations for the study, used Clincalc with G-Power 0.80, set the alpha value at 0.05 and the beta value at 0.95, and use a 95% Confidence Interval as the tools [3].

The computer with a Ryzen 3 processor, 8GB of RAM, a 1TB hard drive and a 256GB solid-state drive was used to perform the testing for this study and software specifications including the Windows 11 operating system, the Chrome web browser, and SPSS software for statistical analysis.

The datasets used in this research were obtained from GitHub, specifically from the file named "kerala. csv" in the "Flood-Prediction-Model" repository, with a datafile extension of CSV. The type of data in the dataset is text. The planned training and testing ratio for the dataset is 80:20, with a total of 120 records and 15 attributes, including YEAR, JAN, FEB, MAR, APR, MAY, JUN, JUL, AUG, SEP, OCT, NOV, DEC, ANNUAL RAINFALL, and FLOODS. The dataset was divided into two separate datasets for the purpose of training and testing [5].

2.1. Novel recurrent time delay neural network

A type of ANN that can handle data that changes over time, such as speech or data from climate change and time series using NRTDNN. Novel Recurrent Time Delay Neural Network use a pooling layer that delays the input to the network by a certain amount of time, allowing them to capture temporal dependencies in the data. This means that the network can process the data while taking into account the order in which it was generated. NRTDNNs are commonly used for tasks such as time series flood forecasting, language modeling, and speech recognition [8].

2.1.1. Procedure for Novel recurrent time delay neural network

1. Define the cost function and the learning rates and desired matrices.
2. Initialize the training epoch and set a threshold value for the error.
3. For each epoch, do the following:
4. Extract the data from the dataset
5. If the error is greater than the threshold value, repeat the epoch

6. Run the optimizer and compute the average cost
7. Evaluate the current test accuracy percentage
8. Display the results and calculate the final test accuracy percentage

2.2. Guassian Naive-Bayes

Using the Bayes theorem and assuming that no two features are related, GNB is an algorithm that can sort data into different categories. It is called "naive" because it assumes that all of the features in the data are independent, which is a strong assumption that is not always true in real-world data. Despite this assumption, the algorithm often performs well in practice. The Gaussian Naïve-Bayes algorithm assumes that the continuous features in the data follow a normal (Gaussian) distribution. Given a set of training data, the algorithm estimates the mean and variance of each feature for each class. These estimates are then used to classify new samples based on the likelihood that they belong to a particular class. Gaussian Naive-Bayes is often used for text classification tasks, such as identifying spam emails or classifying news articles by topic. It is also used in image classification tasks and for predicting the flood forecasting likelihood of an event occurring given a set of features [7].

2.2.1. Procedure for Guassian Naive-Bayes

Input:
  Dataset training T.
  F=(f1,f2,f3,fn)
  Output:
  Dataset testing.
  Steps:
1. Process the input
2. For each class, calculate the mean and the standard deviation of the predictor variables
3. Continue once the probabilities of all the predictor variables (fi, f2, f3,..., fn) have been determined, calculate the likelihood of fi in each class, use the Gaussian distribution formula.
4. Determine the probability of class
5. Acquire the best chance

2.3. Statistical analysis

The statistical analysis in this study was performed using IBM SPSS V26.0 software, the analysis involves various statistics, such as the average mean (M), standard deviation (SD) and standard error. The research also involved the use of an independent t-test analysis with dependent variables and independent variables. The Independent variables are Year, Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec and dependent variables are flood level [18].

3. Tables and Figures

Table 126.1. Group Statistics. The Mean of the Novel Recurrent Time Delay Neural Network. algorithm is 91.40 and the Gaussian Naïve-Bayes mean value is 86.41. The below will show the NRTDNN Std. Deviation (0.701) and Std. Error Mean is (0.128)

	Algorithm	*N*	*Mean*	*Std. Deviation*	*Std. Error Mean*

4. Results

The novel recurrent time-delay neural network, which is a discretized version of a continuous-time recurrent unit governed by delay differential equations, outperformed the existing GNB algorithm in flood prediction accuracy.

A comparison of the precision percentage between the NRTDNN algorithm and the GNB algorithm is shown in Table 126.1. A comparison between the NRTDNN algorithm and the GNB algorithm showed that the former had a higher accuracy percentage of 91.40%, while the latter had an accuracy of 86.41%.

The SD for NRTDNN was lower than that of GNB, with values of 0.701 and 0.128 respectively.

An independent sample T-test was performed to compare the performance of NRTDNN and GNB. The result showed a significance value of 0.000 (p<0.05), indicating that the difference between the two algorithms was statistically significant. The t value was 27.559, and df were 58 for both NRTDNN and GNB.

The accuracy comparison between NRTDNN and GNB algorithms is also visualized in Figure 126.1, which is a simple bar graph with error bars representing +/- 1 standard deviations, with a confidence level of 95%. The graph confirms that NRTDNN (91.40%) had a higher accuracy than GNB (86.41%).

5. Discussion

The results of this study showed that the NRTDNN algorithm outperformed the GNB algorithm in terms of accuracy. The NRTDNN algorithm achieved an accuracy rate of 91. The NRTDNN algorithm significantly improved the accuracy of flood prediction, making it more likely to accurately predict these events. This article found that the SVM algorithm had the highest accuracy rate for flood prediction compared to other algorithms, due to its ability to perform both prediction and classification tasks effectively. The DNN-NRTDNN algorithm was also found to provide accurate flood prediction techniques. Overall, the results of this study suggest that these algorithms can be useful for improving flood prediction [20]. The author also presented a graphical representation of the use of

Time Delay Neural Networks for flood prediction. In this article, the author analyzed the performance of several Machine Learning algorithms, including MLP, GNB, KNN, and DNN, for the purpose of improving flood prediction. The NRTDNN algorithm was found to produce the best results among all of these algorithms. Overall, the results of this study suggest that utilizing the ML algorithms can be effective in improving the accuracy of flood prediction.

6. Conclusion

This study found that the Novel Recurrent Time Delay Neural Network algorithm had a higher accuracy rate for flood prediction (91.40%) compared to the Gaussian Naïve-Bayes algorithm (86.41%). This study demonstrates that the NRTDNN algorithm can enhance the performance of flood forecasting and showed promising results in terms of accuracy and reliability compared with the GNB algorithm with flood forecast dataset.

127 Detection of player movements in indoor stadium using you only look once algorithm compared with GoogleNet algorithm

Shaik Khasim Saida[a] and V. Parthipan

Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: This study aims to detect the player movements and motions in indoor games stadiums to enhance accuracy by using you only look once and GoogleNet. There are two groups in this study: You Only Look Once and GoogleNet algorithm. The sample size for each group is 10, determined using ClinCalc online software with a 95% confidence interval and an alpha value of 0.05. The object detection in indoor stadium dataset with a size of 1500 images was collected from Kaggle.com. It was discovered that the proposed technique obtained 94.450% accuracy when compared to the current system, which has an accuracy of just 91.580%, and that there is a statistically significant difference between the YOLO Model and GoogleNet model with a value of p= 0.000 (Independent sample t-test p<0.05). Experimental results show that the You Only Look Once algorithm detects moving objects in indoor stadiums significantly better than the GoogleNet method.

Keywords: GoogleNet, MobileNet, novel object detection, roads, tensorflow, transport, vehicles, you only look once

1. Introduction

The process of using computer vision algorithms to detect and label objects in a video clip is referred to as new object detection, and it is a challenging task to track moving targets or objects in real-time video. One of the methods is the deep neural network, which uses hidden layers to significantly improve the accuracy of new object detection in videos powered by Tensorflow. R-CNN was introduced in 2014, which is based on the deep convolutional neural network and was initially used as the detection technique. YOLO is able to identify transport vehicles on the roads using the image it has collected. In order to use the MobileNet technique, tensorflow, which makes use of depth-wise separable convolution, in order to significantly reduce the size of the parameters as compared to standard convolution filters of the same depth is cited 38 times. SSD post-processing is used to adjust the bounding boxes and rescore the boxes based on the other items in the frame after segment. Post-processing is used to fix the

bounding boxes and rescore the boxes based on the other items in the frame after categorization. In review of the research gap, it was determined that the previous work is insufficiently accurate to detect moving objects. The purpose of this study is to increase perceived accuracy by using You Only Look Once over GoogleNet. The goal of this study is to use You Only Look Once over GoogleNet for improved accuracy.

2. Materials and Methods

To enhance the GoogleNet classifier and the You Only Look Once Model has been discussed in this work. Utilizing the N=10 sample size with a G power of 80%, a threshold of 0.05%, and a CI of 95%. The mean and standard deviation have been collected from previous studies in order to determine sample size. Each group has a sample size of 15 and two groups to carry out the recommended and current machine learning approaches. The calculation is done with G-power 0.8,

alpha-0.05, and beta-0.2, with a 95% confidence level [8] (https://clincalc.com/stats/samplesize.aspx).

An 8 GB RAM, Intel 10th generation i5 processor, and a 2 GB graphics card make up the testing environment, which also includes SPSS version 26.0.1 and the Matlab IDE [13]. The object detection in indoor stadium dataset with a size of 1500 images was considered from Kaggle.com. Slicing is used to reduce the dataset, after which it is evaluated and tested with Matlab tailored to the setting.

3. You Only Look Once (YOLO)

Finding instances of semantic items of a specific class (such as people, buildings, or cars) in digital photos and videos is the subject of the field of computer science known as novel object detection, which is connected to computer vision and image processing. Face and pedestrian detection are two thoroughly studied topics of novel object recognition. It introduces YOLO, a modern method of discovering new things. The detection of novel objects is now seen as a regression problem to spatially distinct bounding boxes and associated class probabilities. In a single assessment, a single neural network can immediately predict bounding boxes and class probabilities from the entirety of an image. Because the entire detection pipeline is made up of a single network, the detection performance may be altered from beginning to end. Our primary YOLO model performs real-time, 45 frames per second photo processing. At a frame rate of 45 frames per second, our fundamental YOLO model processes images in real time. Our core YOLO model processes photos in real time at a frame rate of 45 frames per second. Even at its reduced processing speed of 155 frames per second, Fast YOLO outperforms other real-time detectors in mAP by a factor of two.

3.1. Procedure

Step 1: Import the necessary photos, then create a function to filter the boxes based on probabilities and thresholds.

Step 2: Build a function that calculates the AOI.

Step 3: Develop a Non-Max Suppression function.

Step 4: After using the shape to generate a random volume, predict the bounding boxes (18,18,4,84).

Step 5: Construct a way to foresee the bounding boxes, then save the images with these bounding boxes in place.

Step 6: Make predictions after reading an image with the forecast tool.

Step 7: Yolo eval can be used to predict a random volume.

Step 8: Utilize the threshold algorithm to convert the preprocessed image to a binary image.

Step9: Segment each unique Object that is visible in the picture.

Step 10: Using the average values of the geometric characteristics' major axis, minor axis, and area, do a quality analysis on each unique object.

3.2. GoogleNet

A convolutional neural network design called AlexNet introduced the concept of consecutively layered convolutional layers in 2012. The AlexNet designers used graphics processing units to train the network (GPUs). The quick development of very effective solutions to common computer vision problems was facilitated by the introduction of CNN, larger datasets, effective processing resources, and intuitive CNN structures.

Researchers found that adding layers and units to a network significantly improved performance. However, adding more layers to build larger networks had a price. Large networks are more likely to overfit and have either an inflating gradient problem or a vanishing gradient problem. Most of the issues that huge networks had were resolved by the GoogleLeNet architecture, primarily through the use of the Inception module. The Inception module is a neural network design that uses dimensional reduction to lower the computational cost of training a large network while leveraging feature identification at various sizes through convolutions with various filters with API. Using the image captured, YOLO can detect Transport vehicles on the Roads.

Another name for GoogleNet is Inception Network. It is a reliable model that offers an answer to problems with segment and detection. It has three more levels, making it deeper than VGG. It has more options for completing the assignment during training. The input can either be instantly pooled or convolved. The ultimate design contains a lot of inception modules that are set up in a sequential way. The training is somewhat different from GoogleNet compared to Inception Network. The neural network is trained more quickly by GoogleNet than by Visual Graphics Group. The pre-trained GoogleNet's scope is greater than VGG.

3.3. Pseudocode for GoogleNet

Step 1: The input to GoogleNet is an image, typically with a resolution of 224x224 pixels.

Step 2: The input image is passed through a series of convolutional layers with different filter sizes and depths. These layers extract features from the input image and create a set of feature maps.

Step 3: After each convolutional layer, a pooling layer is used to down sample the feature maps. This reduces the spatial dimensions of the feature maps and helps to reduce overfitting.

Step 4: The key innovation of GoogleNet is the use of Inception modules, which are designed to capture spatially varying patterns at different scales.

Step 5: An Inception module consists of multiple parallel convolutional layers with different filter sizes and depths, followed by a pooling layer. The output of each parallel branch is concatenated to form the final output of the module.

Step 6: After several Inception modules, the feature maps are flattened and passed through a series of fully connected layers. These layers perform classification by mapping the features to the output classes.

Step 7: The final layer of the network uses the softmax function to convert the outputs of the last fully connected layer into class probabilities.

Step 8: The output of the network is the predicted class label for the input image.

3.4. Statistical analysis

The proposed and compared algorithms statistical analysis is performed using the IBM SPSS 26.0.1 application. The dataset's dependent variables are the scales and item columns. The independent variables in the dataset are store, date, and item. The independent sample T-test analysis has been used to both suggest and compare methods. These algorithms' object identification precision will show that the You Only Look Once (YOLO) Model outperforms the GoogleNet model with more precision [24].

4. Results

Table 127.2 displays the average precision scores of the You Only Look Once and GoogleNet models. The You Only Look Once model demonstrated an accuracy of 94. These results indicate that the You Only Look Once model has a greater accuracy compared to the GoogleNet model. The results indicate that the You Only Look Once model performed better than the GoogleNet model. Specifically, the mean accuracy of the You Only Look Once model was 94. Additionally, the standard deviation of the GoogleNet model was 0. Furthermore, the standard error mean of the You Only Look Once model was 0. Table 127.4 exhibits the outcomes of the independent sample T-test conducted between the You Only Look Once model and the GoogleNet model. Figure 127.3 compares the accuracies of You Only Look Once model and GoogleNet model using the linear graph representation. It shows the YOLO algorithm and GoogleNet Model in terms of mean accuracy.

5. Discussion

The GoogleNet and the You Only Look Once (YOLO) Model were contrasted in this research study. It performed an efficient analysis of moving novel object detection in the indoor stadium using the You Only Look Once and GoogleNet. You Only Look Once (YOLO) has an accuracy value of 94.45% and GoogleNet is 91.58%. When compared to GoogleNet, the You Only Look Once model is more accurate.

Building a machine learning model that can reliably recognise the photos of moving objects is the recommended solution [11]. When an object is stable in one location, it can be simple to photograph it, but it can be difficult to foresee the image when the object is moving [12]. As a result, when it comes to games, it is

difficult for the referee to distinguish between the players on the pitch when they are in motion [22]. These kinds of challenging problems are typically amenable to machine learning. [18]. The analysis of this kind of data by humans is more time-consuming. By leveraging the prior data, helping the algorithm comprehend the pattern, and enhancing the model's accuracy by changing parameters, machine learning can be used to determine if an object's position was stable or not [16]. The best model for segment can be utilized after many techniques have been compared [20].

Though it appears that the suggested You Only Look Once (YOLO) model outperformed the present strategy, there are certain limitations for this study [4, 11]. The system can only forecast an object based on an image; it is unable to track a moving object using sound. This project may one day be put into the cloud. More data can be used to put this into practice.

6. Conclusion

The proposed study utilizes the You Only Look Once (YOLO) Model and the GoogleNet Model for detection of objects in indoor stadiums. The model produces the You Only Look Once (YOLO) accuracy is 94.45% whereas GoogleNet produces 91.58% accuracy.

128 An innovative multiauthority attribute based signcryption using advanced encryption standard algorithm comparing with Fernet algorithm to enhance accuracy

G. Ruchitha[1,a] and S. Radhika[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Research Guide, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The research work intends to enhance the efficiency of Authority attribute based Signcryption with Advanced standard compared to Fernet Algorithm. Here multi authority attribute based signcryption is a cryptographic scheme to jointly sign while encrypting a message in such a way that only authorized recipients can decrypt and verify the signature Novel Multi authority Attribute Based Signcryption is useful in scenarios where multiple authorities need to collaborate to sign and encrypt messages, such as in cloud computing and group communication. Materials and Methods: Execution of Advanced Encryption Standard Algorithm and Fernet Algorithm is done with differing training and testing splits for forecasting the Efficiency of Novel Multi authority Attribute based Signcryption. The test used along with Gpower is about 80%. Result: Advanced Encryption Standard Algorithm (95.73%) has the increased accuracy over Fernet Algorithm (85.44%), loss for advanced encryption algorithm (4.26%) and Fernet Algorithm (114.55%). The significance value was examined and this work presented a value of significance p=0.001. That is, there is insignificant difference between the two groups. Conclusion: The precision value of the AES is 95.73% whereas the precision value of Fernet is 85.44%. Depending on the analysis, the Advanced Encryption Standard algorithm outperforms the Fernet Algorithm.

Keywords: Advanced encryption standard, fernet, novel multi authority, attribute, signcryption, security threats, privacy

1. Introduction

The cryptographic scheme comprising the features of both digital signature and method of encryption to provide confidentiality, authenticity, integrity and non-repudiation is referred to as attribute-based signcryption. The findings from this experiment include the method where the signer needs acquiring one and the other identity-connected keys and assign connected keys in order to create a secret key for an attribute with 78% to 80%. In a CP ABE system, there may be more than one authority, and each authority may issue characteristics and keys independently of the others over 85% [1, 4]. The network makes use of both a central authorities and a number of attribute authorities. The fact that the Central authorities may decrypt any ciphertext in the system is one of the system's major flaws. This makes it more difficult for users to

maintain their privacy and the secrecy from security threats of their data. The proposed technique may provide secrecy from security threats and has been shown to be safe in the standard model. It is best since the use of multi-layer policy and because the theoretical and real word analyses were taken. This study compares the performance of AES and Fernet in order to increase classification accuracy. The proposed model improves the efficiency of Novel Multi authority Attribute based Signcryption to eliminate security threats to individuals and protect privacy.

2. Materials and Methods

The venue of the research was at the Cryptography lab in the Department of Computer Science and Engineering at Saveetha School of Engineering. Sample size was calculated by comparing both the controllers. Two different groups were chosen and their result is derived [12]. 10 samples were selected for this study. Technical Analysis software was used to implement the two algorithms' AES and Fernet.

Python software was used to develop and carry out the proposed work. A 4GB RAM and a processor of Intel Core i7 was made up as the hardware setup.

3. Advanced Encryption Standard (AES)

The Advanced Encryption Standard, a cryptographic algorithm standard that can be used to secure electronic data, has been approved by the Federal Information Processing Standards. The Advanced Encryption Standard (AES) algorithm can cypher and decode data in blocks of 128 bits when using cryptographic keys with lengths of 128, 192, and 256 bits, respectively. The algorithm makes reference to these lengths.

Advanced Encryption Standard processes bytes, not bits. The encryption handles 128 bits (16 bytes) of incoming data at a time because of the block size. Key Schedule algorithms calculate round keys from the key. The starting key generates several round keys for each encryption cycle.

Algorithm for Advanced Encryption Standard algorithm:

Step 1: Introduce the advanced encryption algorithm

Step 2: Arrange a 4x4 matrix of plaintext blocks

Step 3: Create a circular/round key

Step 4: Perform required operations on a matrix of size 4

Step 5: Leave out the last round's MixColumns() step.

Step 6: Send plaintext back

4. Fernet

Data is encrypted and authenticated symmetrically using the Fernet formula. It is a component of Python's cryptography library, which was created by the Python Cryptographic Authority (PYCA). Fernet is built on a number of cryptographic primitives which make up the building blocks. Using Fernet instead of linking the cryptographic primitives might avoid the risks involved in developing individual crypto.

Functions for key generation, encrypting plaintext to ciphertext, and decrypting ciphertext to plaintext are all incorporated into the Fernet module of the cryptography package. Data encrypted with the Fernet module is guaranteed to be unreadable and unmodifiable without the key. This function, generate key(), creates a new Fernet key. The key is the most crucial piece in the puzzle to decipher the ciphertext, hence it must be kept secure at all times. The recipient will no longer be able to read the encrypted communication if the key is misplaced. An intruder with the key can read and forge data. In addition, an intruder or hacker who obtains the key can both read and alter the information.

The encrypt(data) function encrypts the parameter. The ciphertext, or "Fernet token," that results from this process is encrypted using the Fernet cypher. Token encryption additionally includes a timestamp of its plaintext creation. If the data is not in bytes, the encrypt method will throw an error.

The Fernet token is decrypted using the decrypt(token,ttl=None) function. In case of a successful decryption, the original plaintext is recovered; otherwise, an exception is raised.

Steps for Fernet Algorithm:

Step 1: Import the Fernet module

Step 2: Use cryptography package

Step 3: Generate keys

Step 4: Convert plaintext to ciphertext

Step 5: Display of ciphertext

Step 6: Decryption of the ciphertext

Step 7: Displaying of the plaintext

5. Statistical Analysis

The software SPSS is used to undertake the analysis of the Advanced Encryption Standard and the Fernet Algorithms statistically. Images, videos, text, PDF files, and documents all function independently. The size of the file is among the dependent variables [2]

6. Results

With a sample size of 10, the suggested Advanced encryption standard algorithm and Fernet were tested at various intervals in Anaconda Navigator.

Table 128.1. Accuracy and loss analysis of AES

Iterations	Accuracy (%)	Loss (%)
1	98.42	1.58
2	94.95	5.05
3	97.78	2.22
4	94.81	5.19
5	95.09	4.91
6	92.34	7.66

Table 128.5. Comparison of the AES and Fernet with their accuracy

Classifier	Accuracy(%)
AES	95.73
Fernet	85.44

Source: Author.

Table 128.1 reflects the accuracy and loss of AES as predicted.

Table 128.2 depicts the accuracy and loss of prediction made by Fernet. It can be seen from the findings that Fernet had an accuracy of 86.50% and AES of 87.32% on average.
Figure 128.1. Comparison of AES and Fernet in terms of mean accuracy and loss. The mean accuracy of AES is better than Fernet; Standard deviation of AES is slightly better than Fernet. X Axis: AES vs Fernet and Y Axis: Mean accuracy of detection with +/- 1 SD at 95% CI.

Source: Author.

Table 128.3 reflects the average accuracy values for both Fernet and AES. With standard deviations of 6.06 and 4.41, respectively, the mean value of AES is superior to that of Fernet.

Table 128.4 demonstrates the Independent Sample T Test (p<0.05) results for AES and Fernet with a significance value of p=0.001.

Table 128.5 shows the comparison of the Advanced Encryption Standard and Fernet Algorithm with their accuracy. The final accuracies obtained by the comparison of Advanced Encryption Standard Algorithm and Fernet Algorithm are mentioned.

Figure 128.1 indicates the comparison of Advanced Encryption Algorithm and Fernet Algorithm in terms of mean accuracy and loss.

AES has a mean of 95.73, a standard deviation of 2.07, and a standard error mean of 0.65. Similar figures may be found for Fernet: 85.44, 1.43, and 0.45 respectively. AES's loss are 4.26, 2.07, and 1.43, respectively. The Fernet loss values for mean, standard deviation, and standard error mean are, respectively, 14.55, 0.65, and 0.45.

7. Discussion

AES appeared to be superior to Fernet in the investigation at hand because the significant value was p=0. Accuracy of the AES is analyzed as 95. 73% whereas the accuracy of AES is 85.44%. The supporting findings of this research is as follows, a certificate-free aggregate sign-encryption system is proposed to eliminate security threats related to cloud storage. The AES encryption algorithm is combined with ciphertext policy attribute-based encryption and a dual proxy model for a total of TWO layers of encryption. About 79% accuracy was reached. The opposing findings of this research is as follows, This work proposes a method for utilizing elliptic curve cryptography to accomplish effective multi-receiver heterogenous signcryption. The research on PMDC-ABSE made it quite realistic in privacy preservation and the data access with the accuracy of 85.3%. Taking a long time to train the AES algorithm with large datasets is one of the major limitations of this study. The system can be extended to include a larger number of objects with lesser time consumption in training the data set and this gives the future scope.

8. Conclusion

Improvement of the efficiency of Novel Multi Authority attribute based signcryption is performed for AES and Fernet. AES is known to be more secure and provide better accuracy than Fernet Algorithm. This is because AES uses a larger key size, which makes it more difficult to break the encryption. Additionally, AES has been extensively tested and evaluated by experts, making it a trusted encryption algorithm.

129 Prediction of locational electricity marginal prices with improved accuracy by using the Lasso algorithm over linear regression algorithm

P. Praveen Kumar Reddy[1,a], N. P. G. Bhavani[2], and J. Femila Roseline[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Research Guide, Department of Electronic Instrumentation System, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: This research's aim is to increase the accuracy rate of locational electricity marginal prices by comparing Lasso algorithm with linear regression using machine learning techniques. Materials and Methods: The datasets of this research are gathered from Kaggle. The total sample size was 40. Group 1 contains 20 samples and Group 2 also contains 20 samples. The analysis was conducted using a statistical power (G-power) of 0.8, with significance levels (alpha and beta) set at 0.05 and 0.2, respectively. The confidence interval (CI) utilized for the results was at the 95% level. The analysis was done in order to support an improved technique in the SPSS Tool. Results: Based on the result, we observed that the precision of the innovative Lasso algorithm is 95.56% and Linear regression algorithm is 89.76%. The independent sample t-test significance values obtained as 0.001 ($p<0.05$). When we execute both algorithms we can observe partial differences in their test size values. Conclusion: The proposed innovative Lasso algorithm achieves a greater rate of accuracy than the Linear regression algorithm model for predicting the locational electricity marginal prices.

Keywords: Electricity bill, innovative lasso algorithm, linear regression algorithm, electrical power, machine learning

1. Introduction

To accurately reflect the spatio-temporal variations in energy supply and demand, it is necessary to incorporate the operational constraints of energy structures into the LMP calculation. By doing so, we can ensure that the LMP accurately reflects the true cost of energy production and consumption, taking into account the complexities of electrical power systems. It is important to ensure that any formulation or idea related to LMP is presented in a manner that avoids plagiarism, which can be achieved by properly citing all sources used in the development of the idea [19, 21, 27]. The growing prevalence of renewable energy sources presents challenges for energy systems due to the inherent uncertainty in their performance. In order to maintain power balance, the thermal power plants in the system must adjust their power output, resulting in changes to the power flow within the system. The cost of supplying electrical power is subject to constant fluctuations, which can vary from one minute to the next. These price changes are typically driven by shifts in electricity demand, the availability of different sources of generation, fuel costs, and the overall availability of power plants. This is due to the fact that more expensive generation sources are often brought online to meet the increased demand, which drives up the overall cost of electricity. It is crucial to select an

appropriate model in order to attain the desired level of accuracy for future values. The primary aim is to predict the accuracy of electricity prices using Lasso Algorithm which is more effective when compared to Linear Regression.

2. Materials and Methods

Investigation of the research took place in the Department of Computer Science and Engineering at Software Laboratory in Saveetha School of Engineering. For the Electrical power data-sets were taken from the Kaggle website. Each algorithm's total sample size was 40. Group 1 and Group 2 have 20 samples. The sample size was established based on findings and data obtained from prior research studies [28] at ieeexplore.com. The threshold value is 0.05, the G power value is 80%, and the confidence interval was 95%. The simulation has been done in JUPYTER software.

2.1. Lasso regression

To implement a Lasso algorithm for electricity bill prediction, the following steps can be taken:

1. Data Collection: Obtain historical electrical power usage and billing data and clean it to make it usable for predictions.
2. Feature Identification: Determine the crucial features, such as temperature and day of the week, that will be utilized for predictions.
3. Data Partitioning: Divide the data into two parts, one for training the algorithm and the other for evaluating its accuracy.
4. Model Training: Train the Lasso algorithm using the training set and allow it to learn the relationship between the chosen features and electricity bills.
5. Model Evaluation: Evaluate the performance of the trained model by comparing the predicted electricity bills with the actual bills using the testing set.
6. Parameter Optimization: Fine-tune the Lasso algorithm's parameters, such as the regularization strength and iteration count, to enhance its accuracy.
7. Deployment: Deploy the optimized Lasso model for making electricity bill predictions in the future.

2.2. Linear regression

Supervised ML algorithm is used for predicting a continuous dependent variable based on one or more independent variables. It posits a linear correlation between the independent variables and the dependent variable.

The goal of linear regression is to minimize the difference between the predicted values and the actual values of the dependent variable.

The following are the stages for utilizing machine learning to construct a linear algorithm for locational electricity marginal price (LMP) prediction:

1. Start by collecting data related to locational electricity marginal price (LMP), weather, house area, TV, AC, electricity consumption, and any other relevant factors. The data should comprise the LMP at different locations and times, along with elements that may have an impact on the LMP, such as weather and electricity demand.
2. This stage involves several tasks such as cleaning the data to remove any inaccuracies or inconsistencies, dealing with missing values by either removing them or imputing them, converting variables to make them suitable for modeling, and normalizing the data to standardize its format and range. These steps help to ensure that the data is ready for use in the modeling process.
3. The selection of features plays a crucial role in the modeling process. To determine which features will be used, one must consider the available data and identify the relevant factors that could impact the model's outcome. This may include analyzing LMP at different locations and time intervals, examining the weather conditions, house area, TV, AC, evaluating electricity demand, and considering any other pertinent factors. The goal is to choose the features that are deemed most important and will contribute the most to the model's accuracy.
4. In order to make predictions, it's important to choose the appropriate model type. A linear regression model is frequently used for Locational Marginal Price (LMP) prediction as it is straightforward and offers clear interpretability.
5. Once the features and data have been chosen, the next step is to train the model. To achieve a reduction in the error between the predicted values and the actual values in the data, one can fine-tune the model's parameters.
6. After training the model, it's crucial to assess its performance by comparing its predictions to the actual Locational Marginal Price (LMP). This evaluation can be carried out by calculating various performance metrics, such as MAE, RMSE, or MSE.
7. To enhance the efficiency of the model, modifications can be made by tweaking its parameters, altering the features utilized, or opting for a different model altogether. This process is known as fine-tuning.
8. Once the model has reached its peak performance, it can be implemented in practical applications by being deployed in a real-world environment. This deployment allows the model to make predictions on newly obtained LMP information.

2.3. Statistical analysis

The two groups are Innovative Lasso Algorithm and Linear Regression Algorithm were performed in the SPSS version. The independent variables in the research were AC, TV, etc. and the dependent variable is Electricity prices, Linear Regression Algorithm etc. In the innovation system and existing system, algorithms and calculations were performed within 40 samples. The 2-tailed sig. value is 0.001 (p<0.05). The sample values for both algorithms were exported to SPSS software to determine the result of both algorithms. The accuracy value was obtained successfully in the simulation of the code. It obtained the time and efficiency successfully by simulating the code in the software [7].

3. Result

Table 129.1 presents a comparison of the accuracy of predictions made using the Innovative Lasso and Elastic Net algorithms. Each algorithm has a data set size of 20. The table displays the accuracy values of both the Lasso and Elastic Net algorithms for different inputs.

Table 129.2 displays the outcomes of a T Test, which contrasts the mean, group size, standard deviation, and standard error mean when applying the Innovative Lasso Algorithm and Linear Regression techniques for forecasting electricity bills through machine learning approaches. The group size used in the research is 20, and the mean accuracy values for the Innovative Lasso Algorithm and Linear Regression are 95.56 and 89.76, respectively. The SD is 1.81802, and the SEM is 0.40652 for both algorithms.

Table 129.1. The prediction accuracy of the innovative Lasso and Elastic Net algorithms has 20 samples per algorithm. The accuracy values for the Lasso and linear regression algorithms for various inputs

Test Sample size	Accuracy of Lasso algorithm (%)	Accuracy of Linear regression (%)
1	95.56	89.76
2	94.56	88.77
3	95.26	89.46
4	94.36	88.56
5	94.58	88.79

Figure 129.1. The accuracy of the Innovative Lasso Algorithm classifier to that of the Linear regression algorithm has been evaluated. The research paper has a mean accuracy of 95.56%, whereas the Linear regression classification algorithm has a mean accuracy of 89.76%. The X-axis of the graph represents the precision rates of both algorithms, Y-axis displays the mean keyword identification accuracy +/-1SD, 95% CI.

Source: Author.

Table 129.3 has the research conducted a statistical analysis of the independent variables in the Innovative Lasso Algorithm and compared it with the Linear Regression classifier. The statistical significance level for the accuracy rate was found to be 1.000. An independent sample T-test was conducted to assess the performance of the Lasso and Linear Regression algorithms. The test employed a 95% confidence interval and a significance threshold set at 0.57491. The results of the test indicated that the significance level was 1.000, implying that there was no statistically significant difference between the two algorithms. However, when considering a two-tailed significance test, the p-value was found to be 0.001, which is less than the conventional significance threshold of 0.05 (p<0.05). This suggests that there is indeed a significant difference in performance between the Lasso and Linear Regression algorithms. Specifically, the mean difference between their performances was calculated to be 5.8000, with a standard error difference of 0.57491.

Figure 129.1 illustrates a comparison of the accuracy between the Innovative Lasso Algorithm and the Linear Regression Algorithm. The Innovative Lasso Algorithm exhibits an average accuracy of 95.56 %, whereas the Linear Regression Algorithm demonstrates an average accuracy rate of 89.76 percent. The data unequivocally indicates that the Innovative Lasso Algorithm outperforms the Linear Regression Algorithm in terms of accuracy. This observed difference between the two algorithms is statistically significant (p < 0.05) according to an independent sample test. On the graph, the X-axis represents the accuracy rates of both the Innovative Lasso Algorithm and the Linear Regression Algorithm, while the Y-axis portrays the

mean accuracy rate, complete with a margin of error of +/- 1 standard deviation.

The research found that the accuracy of the Lasso Regression algorithm was approximately 95.56%, while the Linear regression algorithm was approximately 89.76%. The accuracy of both algorithms varied when executed with different test sizes. The algorithms' performance was assessed through Group Statistics, encompassing metrics such as mean accuracy and standard deviation for comparison. The Lasso Regression algorithm was found to be 95.56% as mean accuracy and 0.32 as standard deviation, respectively, while for Linear regression, they were 89.76% and 0.41, respectively. By conducting statistical analysis on 10 samples, the Lasso Regression algorithm obtained a standard deviation of 0.32 with a standard error of 0.10137, while Linear regression obtained a standard deviation of 0.41 with a standard error of 0.13263. The significance value of 0.000 indicated that the hypothesis was better. An independent Sample T-Test was performed to compare the algorithms, and a bar graph was plotted to visualize the results. Finally, the framework for Electricity Bill Prediction was presented. The experimental findings suggested that the Lasso Regression algorithm exhibited superior performance when compared to the Linear Regression algorithm.

4. Discussions

In this proposed methodology, the Locational Electricity Marginal Price prediction system is developed utilizing the Innovative Lasso algorithm and Linear Regression algorithm, and the accuracy of its output is studied and compared. Experiments are conducted by comparing the efficacy and precision of the Linear Regression algorithm method to the proposed Innovative Lasso algorithm system in order to examine the results of the proposed model and give superior results. 56 percent accuracy, outperforming the Linear regression algorithm model, which achieved 89. Residential and commercial consumers typically pay higher prices for electricity at retail because the cost of distributing electricity to them is higher. Industrial consumers, on the other hand, use more electricity and can receive it at higher voltages, resulting in more efficient and less expensive delivery. As a result, industrial customers usually pay a retail price for electricity that is similar to the wholesale price (Holladay, Scott Holladay, and LaRiviere 2018). A major problem in the research of market power is therefore to analyze the price of electrical power to determine the effective drivers of its change ("Current Problems of Static Electricity" 1975). The proposed approach has certain drawbacks due to the inadequate number of labeled datasets available under similar conditions, and the restricted sample size of the datasets utilized in the investigation.

This will lead to the creation of a robust machine learning algorithm for predicting Locational Electricity Marginal Price. The research provides a guideline for future studies in this domain and contributes significantly towards the enhancement of Locational Electricity Marginal Price prediction methodologies.

5. Conclusion

In this research, the two algorithms are compared for improving the accuracy. By obtaining the results can conclude that the innovative Innovative Lasso algorithm results in an accuracy of 95.56% in the estimation of marginal prices from various locations compared to Linear algorithm which results in an accuracy of 89.76%. The Independent sample T test significance is 0.001 (p<0.05). This research shows that the Innovative Lasso algorithm has a high level of accuracy when compared with Linear regression algorithm for forecasting electricity marginal prices.

130 Comparison of accuracy using novel artificial neural network model over logistic regression approach for flood prediction

Hussain Basha M.[a] and Uma Priyadarsini P. S.

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The aim of this research work is to compare flood prediction using Novel Artificial Neural Networks in comparison over Logistic Regression. In this study, two groups were evaluated using the specified methodology with a Gpower 80%. A total of 10 samples each are used for the analysis of Novel Artificial Neural Network and Logistic Regression technique. The suggested Novel Artificial Neural Network technique outperforms Logistic Regression, which has an accuracy of 85.38%, in classification with a precision of 88.51%. An independent sample T-test was conducted and the obtained p-value was 0.011 (P<0.05) which is less than the significance level of 0.05. The results obtained are statistically significant. In terms of prediction, the Artificial Neural Network technique got better results compared to the Logistic Regression algorithm.

Keywords: Novel artificial neural network, logistic regression, time series prediction, artificial intelligence, floods, opinion mining, regression analysis, machine learning

1. Introduction

The objective of the study is to get larger the accuracy of the predictive analysis of Rainfall and Flood rate using Novel Artificial Neural Network. It is challenging to do evaluation study based on just one thing [21, 22]. This approach takes into account a number of variables, including algorithm classification, score measurement, and Time Series Prediction preprocessing [7, 12, 23]. A brand-new field of research in machine learning neural networks. The goals of an evaluation research include classifying assumptions and frequency as well as locating and eliminating subjectivity in the information sources. The predictive analysis of Rainfall and Flood rate using Novel Artificial Neural Network is implemented for the well wishes of society.

There are 21 publications published on Research-Gate and 26 articles relating to this subject in IEEE automated Xplore. The maximum frequency of precipitation is calculated and forecasted depending on the results of the analysis and recording of precipitation [1, 3, 5, 8]. It can be done in two ways: "Positive and Negative" or "Positive," "Negative," and "Neutral". For risk assessment and managing severe development, flood prediction models are quite valuable [10]. It is essential to have cutting-edge Time Series Prediction tools for both short- and longer-term Opinion Mining forecasting of floods and other hydrological events in order to reduce damage. However, because of the Regression Analysis dynamic nature of climate conditions, the forecast of flood lead season and occurrence site is essentially difficult [1]. Physical models are quite good at predicting a variety of flooding scenarios, Floods but they frequently require several forms of hydro-geomorphological measurements records, which require intensive computing, making short-term prediction impossible [8]. Thus, the best flood forecasting methods for both long-term and short-term [15, 16] floods are described in this paper. Additionally, the major developments in improving flood prediction model quality are examined. The most successful ways for enhancing ML methods Regression Analysis are reported to floods by model optimization, algorithm

ensemble, data decomposition, and hybridization [9, 13, 17]. One drawback of the current method is the requirement for a compressed form of data to assess the context of rainfall and flood. Complex data-driven Artificial Intelligence models should be used because of the shortcomings of statistical and physically based models Time Series Prediction outlined above. Data-driven prediction models using machine learning (ML) are promising tools that are simpler to use and less expensive since they can be developed more quickly and with fewer inputs. In addition to performing better than physical models while being less complex, they can be trained, flood validated, tested, and reviewed quickly. The precision of these models will be examined.

2. Methods and Materials

The Logistic Regression Algorithm and a Novel Artificial Neural Network, two machine learning algorithms, were compared in a study at the Artificial Intelligence Lab in the Saveetha School of Engineering. Ten data points were used in the study, split into two groups, and the outcomes were assessed using G Power statistical software [4,14]. The study's real competence was 80%, which is an acceptable degree of performance. It is crucial to Time Series Prediction to remember that the small sample size may restrict the findings' generalizability, and that other considerations should be taken into account in Regression Analysis when interpreting the findings [19,20]. This (kaggle.com/code/mukulthakur177/flood-prediction-model/data) is used to download the dataset for prediction analysis. Year, Months, and Flood are among the 14 traits and 20000 rows of the attributes. The data file is organized as a comma separated value file. G power (alpha = 0.05 and power = 0.80) is used to estimate the number Regression Analysis of cases needed for this search. The most well-known social media network sources, referred to as kaggle, Time Series Prediction were where the data had been gathered. Following Opinion Mining compilation in preprocessing, the dataset cleaning process was used to eliminate all useless values and missing values from the data file. Algorithms are compared in order to determine Artificial Intelligence which is superior. The testing configuration for the anticipated system implementation using the recycled SPSS and Jupiter tools.

2.1. Novel artificial neural network

In a synthetic neural network, the current phase of the process takes the output from the previous step as its input. In Novel Artificial Neural Networks, inputs and outputs are usually independent, but there are scenarios where previous inputs are necessary, such as in predicting the next word of a sentence. To address this issue, a Novel Artificial Neural Network was developed that utilized a Hidden Layer. The Hidden state, which has a memory that stores all the information from calculations, is a critical component of this network. It can recall specific information about a sequence and provides consistent results for each input with the same settings.

Pseudocode of ANN

Step 1: The network is given a single moment step of the input.

Step 2: Then determine its current state using the provided present input and the preceding state.

Step 3: For the crucial transition phase, the current time becomes ht-1.

Step 4: Depending on the difficulty, you frequently blend the facts from all previous states.

Step 5: The final state is used to calculate output once all steps have been finished.

Step 6: The inaccuracy is then shown by contrasting the output with either the actual output or the intended result.

Step 7: In order to develop the network, the error back-propagated to the network that updates weights (ANN).

2.2. Logistic regression

Some of the Machine Learning algorithms that are utilized most frequently in the Supervised Learning category is logistic regression. Using a predetermined set of independent factors, it is applied to forecast the dependent variable that is categorical. Using logistic regression, the result of the dependent variable having a categorical character is predicted. As a result, the result must be an independent or categorical value. Instead of the precise numbers between 0 and 1, it delivers the probabilistic values that fall between 0 and 1. Either True or False, 0 or 1, or Yes or No, are possible outcomes. With a few exceptions of how they are applied, linear regression and logistic regression are pretty comparable. Correct regression issues as opposed to using linear regression, that is utilised to handle classification errors.

Logistic Regression pseudocode

Step 1: identify and gather information.

Step 2: Pre-processing of data.

Step 3: Train dataset T.

Step 4: Logistic regression is fitted to the training set.

Step 5: estimating the test outcome.

Step 6: Test the result's correctness (Creation of Confusion matrix).

Step 7: displaying the results of the test set.

The performance of Novel Auto Encoder and Logistic Regression was assessed through software using Python programming language and a Jupyter notebook. The hardware used for this evaluation consisted of an Intel Core i5 processor with 8GB of RAM. The system was equipped with a GPU-based processor, a 64-bit operating system, and a 1TB hard disk drive. The software configuration included Windows 10 operating system.

2.3. *Statistical analysis*

Independent T-Test analysis for Novel Artificial Neural Network and Logistic Regression was performed using IBM Version 26 of the Statistical Package for the Social Sciences (SPSS), with 10 samples for each group [11]. Dependent variables were used, including standard error analysis, the mean, and standard deviation. This dataset's independent variables include Year, Month, Rainfall, and Flood.

3. Results

Compared to Logistic Regression, Novel Artificial Neural Networks appear to perform marginally better. The accuracy rates for ANN and Logistic Regression are displayed in Table 130.1. Between Logistic Regression and Novel Artificial Neural Networks, there was statistical insignificance. Accuracy is a metric for evaluating the overall effectiveness of predictions.

Table 130.2 The Independent Samples Test (IST) categorizes the test for equality of variances and the T-test for equality of mean for mean differences and

standard error differences. With a sample size of 10, the group statistics in Table 130.2 above include Mean, Standard Deviation, and Standard Error Mean. With a value of 0.011 (p<0.05), the Artificial Neural Network technique seems to perform somewhat better than the Logistic Regression Algorithm.

4. Discussions

The Novel Artificial Neural Network algorithm, which has an accuracy of 88.51%, outperforms the Logistic Regression Algorithm, which has an accuracy of 85.38%, according to the study's findings. The results demonstrated that the algorithm performed better with more training data.

Novel Artificial Neural Networks are among the most popular ML approach in the task due to their accuracy, high tolerance for faults, and effective execution in parallel while processing complicated flood functions, especially in situations when datasets are inadequate. But with ANN, generalization is still a problem (Logistic model trees, Accuracy = 85.38%) [10]. Researchers believe these data decomposition approaches will gain in popularity because they were integrated with ANNs, SVM, WNN, and FR. The other development in the enhancement Opinion Mining of generalization and prediction accuracy is EPS. In fact, modern ensemble Artificial Intelligence approaches have significantly improved generality, accuracy, and speed. (Multilayer perceptron, Accuracy = 81%) [10, 13]. To increase Time Series Prediction the accuracy of prediction categorization of brief data, this research introduces a topic-enhanced recurrent

Table 130.1. The statistical calculations for the Novel Artificial Neural Network (ANN) has mean accuracy of 88.51% compared to Logistic Regression (LR) with mean 85.38%. Standard Deviation of ANN has 1.10920 and for LR algorithm has a value of 3.32915, the Standard mean error ANN is .35076 and the LR is 1.05277

	Algorithm	N (Number of Epochs)	Mean	Standard Deviation	Standard Mean Error
Processing Speed	ANN	10	88.5190	1.10920	.35076
Processing Speed	LR	10	85.3860	3.32915	1.05277

Source: Author.

Table 130.2. The statistical Calculations for Independent variable of Novel Artificial Neural Network (ANN) in Comparison with Logistic Regression (LR) classifier has been evaluated the significance level of the rate of Accuracy is 0.011 (p<0.05)

	Levene's Test for equality of variables		T-Test for equality means					95% confidence interval of the difference	
	f	sig	t	df	Sig 2-tails	Mean difference	Std. error difference	lower	upper
Accuracy	10.405	0.005	2.823	18	.011	3.13300	1.10966	.80168	5.46432
Accuracy	10.405	0.005	2.823	10.974	.011	3.13300	1.10966	.68993	5.57607

autoencoder model. To mine opinions using Natural language processing in the type of sentiment analysis for documents, sentences, and features. The study of client attitudes and opinion mining has received a lot of attention. (Random forest, Accuracy = 87%) [10, 13, 18]. The results showed that increasing the training data improved the algorithm's performance. The efficiency of prediction is determined by calculating training accuracy, validation accuracy, floods, and validation loss [6].

The condition of statistical and physics-based models discussed above encourages the use of sophisticated data-driven models. The ability of such models to be numerically defined another aspect of their appeal is the nonlinearity of floods. This can be inferred Regression Analysis from historical data alone, without the need to understand the underlying physical processes. Prediction models built using machine learning and data are appealing tools because Opinion Mining can be built more quickly and with less inputs. Artificial intelligence is used to generate patterns and regularities. In comparison to physical models, floods, it allows quicker training, validation, testing, and assessment as well as simpler implementation at reduced computing costs.

5. Conclusion

The predictive analysis of rainfall and flood using Novel Artificial Neural Network is implemented for the well wishes of society. The Novel Artificial Neural Network Algorithm has a higher accuracy of 88.51% than the Logistic Regression (LG) Algorithm, with an accuracy of 85.38%, for predicting the flood. Based on this study, the Novel Artificial Neural Network Algorithm has an accuracy of 88.51% compared to the Logistic Regression Algorithm's 85.38%. There has been a significant order of reduction in the temporal complexity.

131 Blind face image restoration using novel generative adversarial network V3 in comparison with deep face dictionary network to improve naturalness image quality evaluator score

Harish M. K.[1,a] and Jaisharma K.[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Project Guide, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The aim is to optimize the Naturalness Image Quality Evaluator (NIQE) score in image restoration process using Novel Generative Adversarial Network v3 (NGAN3) and compare its performance with Deep Face Dictionary Network (DFDNET). Clincalc tool has been used to calculate the sample size of each group (Group 1 and Group 2) and error rate like alpha rate of 0.05, G-power rate of 0.80 and last beta rate of 0.2 is utilized. It consists of two types: group 1 contains NGAN3 and group 2 contains DFDNET in which samples per group contains 20 sample sizes. Therefore, the total number of samples is 40 that have been used in this experiment. The image undergoes degradation due to low resolution, noise in pixels, blurriness, and compression artifacts. This can be measured using the NIQE score of the image, the NIQE score is optimized using the NGAN3 model to improve the quality of the image. The Naturalness Image Quality Evaluator score of group 1 NGAN3 is 4.46 and the NIQE score of group 2 DFDNET is 9.47. Based on the sample t test, the significance value between the two groups is $p=0.000$ ($p<0.05$), which shows the statistical significance between the groups. Both algorithms were compared in which the Novel GAN3 produced more realistic and rich images than the existing.

Keywords: Deep face dictionary network, facial prior, high-quality, image restoration, novel generative adversarial network v3, NIQE, real-world, well-paid jobs

1. Introduction

It is used to create realistic faces with a high degree of variation, provides rich and varied preferences such as geometry, face textures and colors, allows facial details to be restored as well as enhancements in color intensity by facial prior. Photoshop-like applications for face portrait reconstruction and touch up lead to a variety of consumer and film production use cases for well-paid jobs. For this research total of 5 years articles are treated and these articles are extracted from IEEE Xplore along with Science Direct. From IEEE Xplore, a total of 235 articles and 189 articles from Science Direct are measured based on this theme. The article in which the author proposed a novel approach to the rank minimization problem, termed rank residual constraint model in which it outperforms many state-of-the-art schemes in both the objective and with facial prior perceptual quality. The article in which the author proposed an underwater image restoration method based on transferring an underwater

style image into a recovered style using MCycle GAN System in which it shows a pleasing performance on the underwater image dataset. The article in which the author proposed an adaptive TV regularization model for salt and pepper denoising in digital images in which it obtained artifact free edge preserving restorations [1]. The finest among these four is "Multi-scale adversarial network for underwater image restoration" considering it includes a SSIM loss, which can provide more flexibility to model the detail structural to improve the image restoration performance and the method shows a pleasing performance on the underwater image dataset. The existing system has some limitations in which it struggles with restoring faithful facial details or maintaining face identity. So, the proposed system contains rich and diverse priors which are encapsulated in a pre-trained face GANv3 for the restoration of a blind face image and has improved NIQE than the existing system facial prior and also may provide well-paid jobs.

2. Materials and Methods

To determine the sample size for each group (Group 1 and Group 2) and the error rate, the Clincalc tool was used with an alpha rate of 0.05, G-power rate of 0.80, and a beta rate of 0.2. The experiment included two groups: Group 1 with NGAN3 and Group 2 with DFDNET, each with a sample size of 20. Therefore, a total of 40 samples were used in the experiment [2].

The code for this work was compiled and executed using Google Colab, which offers high-end system configurations including an AMD Ryzen 7 4800H Processor, 16GB of RAM, 1TB of SSD, and an NVIDIA RTX 3050 graphics card with 4GB of dedicated video memory. The software used includes Python 3.10, Windows 11, Chrome, and IBM SPSS v26. The code was written in Python language and implemented on my own system [10].

2.1. Novel Generative Adversarial Network v3

In preparation of samples in group 1: Typically, Blind face image restoration depends on facial priors to restore, such as reference geometry prior or facial prior details that are realistic and faithful. The proposed algorithm Novel Generative Adversarial Network v3 incorporates delicate designs in order to achieve a good balance of realism via single pass forward in the real-world [3]. Figure 131.2 represents the functionality of the proposed NGAN3. Specifically, it includes a degradation removal module and also a pretrained face GAN as a facial prior [4].

Pseudocode

Here is the rephrased version of the given procedures:

Build the generator and discriminator networks using the build_generator() and build_discriminator() functions, respectively [5].

Define the generator and discriminator loss functions as binary cross-entropy.

Initialize the generator and discriminator optimizers using the Adam optimizer.

Define the input shape for the generator as (latent_dimension,).

For each epoch in the range of num_epochs:

a. Generate noise samples using the generate_noise() function with batch size and latent dimension as parameters [6].
b. Generate fake samples using the generator network by calling the predict() function with the generated noise samples as input.
c. Get real samples using the get_real_samples() function with batch size as a parameter.
d. Train the discriminator network on real samples by calling the train_on_batch() function with real samples and an array of ones as labels, and calculate the discriminator loss on real samples [7].
e. Train the discriminator network on fake samples by calling the train_on_batch() function with fake samples and an array of zeros as labels, and calculate the discriminator loss on fake samples.
f. Calculate the average discriminator loss as the sum of the discriminator loss on real and fake samples divided by 2.
g. Generate new noise samples using the generate_noise() function with batch size and latent dimension as parameters.
h. Train the generator network on the generated noise samples by calling the train_on_batch() function with noise samples and an array of ones as labels, and calculate the generator loss.
i. Print the epoch number, discriminator loss, discriminator accuracy (if applicable), and generator loss [8].

Repeat the above steps for each epoch in the range of num_epochs [9].

2.2. Deep Face Dictionary Network

In preparation of samples in group 2: Deep Face Dictionary Network is used to guide the restoration of degraded observations and to create deep dictionaries for face components from high-quality images that can be generated using a K-means algorithm [13].

Pseudocode

    Import all libraries

    Import checkpoint file

    Import face dictionary Dictionary Center512

    Import all models in DFDNet algorithm

    Test whole input test image

    Run DFDNet algorithm

    Test img [test img1, test img2,...]

    Face_detection predict human face by comparing to reference based face dictionary

    Crop_test image crop and align

    ROIAlign_Img segment multiscale components row wise to detect in details

    Upscale_Img increase size

    Feature_match multiscale components and reference pre-trained face dictionary

    Test img. Landmark face with multiscale components

    Test img. Restore image

    Input restore image to test image

    Show_result Face restored

    end

    Following is the steps used during the implementation:

1. Set up the environment in Google-Colab [10].
2. Choose runtime type as py and runtime type as GPU for faster results.
3. Now, import basics-r, face-x-lib and other dependencies [11].
4. Upload low quality images for restoration or upscaling [12].
5. Run the program by clicking the start button.
6. Visualize the restored high quality image besides the low quality image.
7. Download the results.
8. Using a niqe score metric can produce a score of the resulting image.
9. The score should be noted in the excel sheet and executed in SPSS v26 software [13].

The dataset which is used in this experiment has been taken from Flickr and the dataset name is Flickr Faces HQ Dataset (FFHQ), Dataset link [4]. There are total of 8 column (attributes) and also a total of 70,000 rows (records/instances) present in the dataset and some of the column names present in the dataset are Photo_url, Photo_title, Author, Country, License, License_url, date_uploaded, date_crawled. The dataset file is in JSON extension, image data is used in this dataset and it has a training and testing ratio planned of ratio 85.7:14.3.

2.3. *Statistical analysis*

For this research IBM SPSS v26 software is used to do statistical analysis [14]. The list of dependent variables present in the dataset are photo_url, photo_title, license_url, license and also the independent variables names are author, country, date_uploaded,

Table 131.1. Demonstrates the Group Statistical analysis for the Novel Generative Adversarial Network v3 (NGAN3) and DFDNET. The Mean NIQE score, Standard deviation, Standard Error Mean for a sample size for 20 samples per group

	Algorithm	*N*	*Mean*	*Std. Deviation*	*Std. Error Mean*

date_crawled. The independent samples T- Test is performed based on the data collected in the excel sheet between the Proposed NGAN3 with existing DFD-NET algorithm [10].

3. Results

The evaluation of the NIQE score for the intervention using the novel NGAN3 indicates that it is significantly more accurate compared to other methods [15]. This suggests that NGAN3 is capable of producing rich and high-quality images, which may have potential applications in various domains, including well-paid job opportunities [16].

Table 131.1 represents each group's statistics and comparison of the NIQE score between two different algorithms in which Novel Generative Adversarial Network v3 is the proposed algorithm and Deep Face Dictionary Network is the existing one [17]. Total number of samples is 40 and the mean NIQE score is 4.46, standard deviation is 0.131, standard error mean is 0.0194 is the outcome for the proposed

algorithm [18]. Whereas mean NIQE score is 9.470, standard deviation is 0.034, standard error mean is 0.005 for the existing algorithm.

Table 131.2 shows the Independent samples Test of both the algorithms. By comparing the NIQE score of the algorithms in equal variances assumed in significance of Two-tailed is 0.00, Mean difference is -5.008, standard error difference is 0.020 and in equal variances not assumed represents significance of two tailed is 0.00, mean difference is -5.008, standard error difference is 0.0201.

Figure 131.1 represents the bar graph of the mean NIQE score of proposed and existing algorithms, in which the proposed algorithm Novel Generative Adversarial Network v3 has a mean NIQE score of 4.46 and for the existing algorithm Deep Face Dictionary Network has 9.47. In the X-axis it contains the algorithms, in the Y-axis it contains the NIQE score of the algorithms. The graph has confidence intervals of 95% and standard deviation of 1 multiplier.

Figure 131.2 depicts the architecture diagram illustrating the functionality of the proposed Novel Generative Adversarial Network v3 (NGAN3). NGAN3 takes low-quality images as input, provided by the user, and generates high-quality output images along with an image quality score. The architecture of NGAN3 is designed to enable this image enhancement process.

4. Discussion

The research work author proposed a CGAN for restoring the underwater images, experiments conducted indicate that the proposed method outperforms existing methods in terms of both visual quality and numerical measures. The research work author implemented GAN which is learned using a large number of real-world images and it is simple, practical modifications to the reconstruction process help keep it within the space of natural images, resulting in more accurate and faithful reconstruction of real images with high-quality. This method has been compared to state-of-the-art techniques, and the experiments show that it performs better on real rain images, producing clear, detailed results. The research work author prefers the SSDL method for accurately restoring high-resolution CT images from low-resolution versions which is efficient, and robust for restoring high-resolution images from noisy low-resolution input. The research work author proposed a survey of GAN inversion, focusing on its key algorithms and applications in image restoration and manipulation. The research work [5] author suggests improving the ability of generators to represent images by making them adaptive to the input and enforcing consistency with observations through back-projections and for

well-paid jobs. It also produces unnatural results for extreme poses, this is because the synthetic degradation and training data used in the method do not accurately reflect real-world conditions. Instead of using synthetic data, it is possible to learn the distributions from real data. By using real data, the distributions will be more accurate and reflective of real-world situations. This can improve the NIQE score of the model and make it more effective in solving real-world problems.

5. Conclusion

Both algorithms were compared, in which the proposed Novel Generative Adversarial Network v3 has a NIQE score of 4.46 and the existing algorithm has a NIQE score of 9.47 (i.e., Lower value represents High performance). The proposed Novel GAN3 produces high-quality, rich images when compared to the existing one and also may provide well-paid jobs. The significance (p) based on t-tests has the value of 0.00, which shows $p<0.05$ and there exists a significance between groups. Based on the NIQE score and significance, the NGAN3 performs better than DFDNET.

132 Comparison of generative adversarial network v3 with Gan Prior Embedded Network in blind face image restoration to improve naturalness image quality evaluator score

Harish M. K.[1,a] and Jaisharma K.[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Project Guide, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The motto is to optimize the Naturalness Image Quality Evaluator (NIQE) score using Novel Generative Adversarial Network v3 (NGAN3) and to compare it with Gan Prior Embedded Network (GPEN) model's performance in terms of image quality. Sample size for each group (Group 1, Group 2) was determined using the Clincalc tool, which was also used to calculate error rates such as the alpha rate of 0.05, the G-power rate of 0.80, and the beta rate of 0.2. The experiment included algorithms of two groups: Group 1 used the NGAN3 algorithm, while Group 2 used the GPAN algorithm. Each group contained 20 samples, for a total of 40 samples. Images may have been damaged or altered in some way, such as by poor lighting, poor image capture, or image manipulation. The NIQE score is optimized using the Novel Generative Adversarial Network v3 (NGAN3) proposed model, which improves the image quality during the pixel restoration. Proposed NGAN3 algorithm had a mean Naturalness Image Quality Evaluator score of 4.46, the existing GPEN algorithm had a mean NIQE score of 7.22. Based on the samples t test, the significance value between the two groups is p=0.000 (p<0.05), which shows statistically significant between the groups. Both algorithms were compared in which the proposed Novel Generative Adversarial Network v3 has a mean of 4.46 and the existing algorithm Gan Prior Embedded Network has a mean of 7.22 (i.e., Lower value represents High performance), Novel GAN3 produces high real and rich images when compared to the existing.

Keywords: Facial prior, gan prior embedded network, high-quality, image restoration, novel generative adversarial network v3, NIQE, real-world, well-paid jobs

1. Introduction

Blind face image restoration is a technique that aims to restoration of the quality of facial pictures. Enhancing the appearance and restoring the image are the goal of this process, to a more usable state as much as possible. These techniques allow for the restoration of facial details and enhancements in color intensity, resulting in high-quality images with a greater level of realism and detail [1]. High cited articles based on the topic are, the article author proposed CNN allows for the analysis of images at multiple scales and the extraction of features that are relevant for image processing tasks [2]. This approach has proven to be effective for a wide range of image processing tasks, including image classification, object detection, and image restoration [3]. This approach has the potential to be a valuable tool for solving a variety of image processing tasks that involve rank minimization. The performance of this approach on an underwater image dataset has

been found to be pleasing. This model has been shown to produce artifact-free, edge-preserving restorations this approach has the potential to be a valuable tool to enhance the quality of noisy pictures [4]. The existing system struggles to accurately restore facial prior and maintain the identity of the face in an image. So, a new system has been proposed that aims to improve the accuracy of reconstructing facial details and facial prior, preserving the identity of the face in images [5].

2. Materials and Methods

The sample size for each group (Group 1 and Group 2) was determined using the Clincalc tool, which was also used to calculate error rates such as the alpha rate of 0.05, the G-power rate of 0.80, and the beta rate of 0.2 [6]. The experiment included algorithms of two groups: Group 1 used the NGAN3 algorithm, while Group 2 used the GPAN algorithm. Each group contained 20 samples, for a total of 40 samples [7].

Google Collab was utilized for code compilation and execution in this work, taking advantage of its high-end system configurations which include an AMD Ryzen 7 4800H Processor, 16 GB of RAM, 1 TB of SSD, and an NVIDIA RTX 3050 with 4 GB of dedicated video memory. The software used includes Python 3.10, Windows 11, Chrome, and IBM SPSS v26. The code was written in Python language and executed on the researcher's own system [8].

2.1. *Novel generative adversarial network V3*

In Group 1 samples, the restoration process of obscured face images involves leveraging facial priors, such as reference geometry and accurate facial details, to reconstruct high-quality images. The proposed Novel Generative Adversarial Network v3 algorithm has been designed to strike a balance between realism and efficiency, utilizing a single pass forward approach [9]. This algorithm is specifically tailored for restoring obscured face images [10].

Figure 132.2 depicts the functioning of the Novel GAN algorithm, which incorporates a degradation removal module to eliminate any loss of quality in the image [11]. The pretrained face GAN serves as a reference for realistic and accurate facial priors [12]. These two components synergistically collaborate to utilize the GAN algorithm for restoring obscured face images.

Pseudocode

1. Build the generator and discriminator networks using the build_generator() and build_discriminator() functions, respectively [13].
2. Set the generator loss function to binary cross-entropy using binary_crossentropy.
3. Set the generator optimizer to Adam using Adam() as the optimizer.
4. Set the discriminator loss function to binary cross-entropy using binary_crossentropy.
5. Set the discriminator optimizer to Adam using Adam() as the optimizer.
6. Define the generator input shape as (latent_dimension,).
7. Start the training loop with num_epochs iterations.
8. Generate noise of size (batch_size, latent_dimension) using the generate_noise() function.
9. Generate fake samples by passing the generated noise through the generator network using generator_network.predict(noise).
10. Get real samples using the get_real_samples(batch_size) function.
11. Train the discriminator network on real samples by calling discriminator_network.train_on_batch(real, np.ones(batch_size)) and store the resulting loss in discriminator_loss_real.
12. Train the discriminator network on fake samples by calling discriminator_network.train_on_batch(fake, np.zeros(batch_size)) and store the resulting loss in discriminator_loss_fake.
13. Calculate the overall discriminator loss as the average of discriminator_loss_real and discriminator_loss_fake using np.add(discriminator_loss_real, discriminator_loss_fake) / 2 and store it in discriminator_loss.
14. Generate new noise of size (batch_size, latent_dimension) using the generate_noise() function.
15. Train the generator network using the adversarial loss by calling gan.train_on_batch(noise, np.ones(batch_size)) and store the resulting loss in generator_loss.
16. Print the epoch-wise losses and accuracies using print(f"Epoch {epoch+1}: [D loss: {discriminator_loss}, acc: {discriminator_accuracy}] [G loss: {generator_loss}]").

2.2. *Gan prior embedded network*

In preparation of samples in group 2: Gan Prior Embedded Network is simple to implement and produces better outcomes [14]. The experiment showed that the proposed GPEN produces significantly better outcomes than state of the art blind face restoration methods, both qualitatively, quantitatively particularly to revive severely tarnished facial images in uncontrolled environments [14].

2.3. *Pseudocode*

```
for epoch in range(num_epochs):
    for batch in training_dataset:
    with tf.GradientTape() as tape:
    real_images = generator(real_images)
```

```
    fake_images = generator(prior(real_images))
    discriminator_loss = discriminator_loss_fn(real_
images, fake_images)
    discriminator_gradients = tape.
gradient(discriminator_loss, discriminator.
trainable_variables)
    discriminator_optimizer.apply_
gradients(zip(discriminator_gradients, discriminator.
trainable_variables))
    with tf.GradientTape() as tape:
    fake_images = generator(prior(real_images))
    generator_loss =
generator_loss_fn(discriminator(fake_images))
    prior_loss = prior_loss_fn(real_images,
fake_images)
    generator_loss += prior_loss
    generator_optimizer.apply_
gradients(zip(generator_gradients, generator.
trainable_variables))
    prior_optimizer.apply_gradients(zip(prior_gradi-
ents, prior.trainable_variables))
```

The steps used during the implementation:

1. Set up the environment in Google Colab for the implementation.
2. Choose GPU as the runtime type to accelerate the processing for faster outcomes.
3. Import the necessary libraries required for the implementation.
4. Provide a degraded image that needs to be upscaled using the implemented algorithm.
5. Start the program and run the image upscaling process.
6. Observe the results obtained from the upscaling process.
7. Download and use the NIQE (Naturalness Image Quality Evaluator) score metric to evaluate the quality of the resulted image.
8. Record the obtained results in an Excel sheet using SPSS v26 software or any other appropriate tool for further analysis and comparison.

For this experiment dataset took from Flickr, the dataset name is FFHQ and dataset link [15]. The dataset for this research consists of a total of 8 columns (attributes) and 70,000 rows (records or instances). Some of the column names in the dataset include Photo_url, Photo_title, Author, Country, License, License_url, date_uploaded, and date_crawled. The dataset for this research is in JSON format and includes image data [16]. The training and testing ratio is planned to be 85.7:14.3, based on an independent samples T-test analysis.

2.4. Statistical analysis

For this research, statistical analysis was conducted using IBM SPSS v26 software on a dataset that comprised dependent variables such as photo_url, photo_title, license_url, and license, along with independent variables including author, country, date_uploaded,

Table 132.1. Demonstrates the Group Statistical analysis for the NGAN3 and the comparison algorithm GPEN, and represents Mean NIQE score, Standard deviation, Standard Error Mean for a sample size of 20 per group

	Algorithm	*N*	*Mean*	*Std. Deviation*	*Std. Error Mean*
NIQE_score	NGAN3	20	4.4624	0.13186	0.01944
	GPEN	20	7.2233	0.07211	0.01063

Source: Author.

Table 132.2. Demonstrates an independent samples T-test between Novel Generative Adversarial Network v3 and the existing algorithm Gan Prior Embedded Network. The significance among the groups shows p=0.000 (p<0.05) and results statistically significant

	Levene's Test for Equality of Variances		*T - Test for Equality of Means*					*95% Confidence Interval of Difference*	
	F	*Sig.*	*t*	*df*	*Sig. (2-tailed)*	*Mean Difference*	*Std, Error Difference*	*Lower*	*Upper*

and date_crawled. An independent t-test was performed to investigate the differences between two groups, namely the proposed Novel Generative Adversarial Network v3 and the existing Gan Prior Embedded Network algorithm, using data collected in an Excel sheet [9].

3. Results

The evaluation of the NIQE score for the intervention, the novel NGAN3 algorithm, revealed that it is significantly more accurate compared to the other algorithm. This suggests that NGAN3 produces high-quality images and has the potential to create well-paid job opportunities [17].

Table 132.1 presents the mean NIQE score of the proposed NGAN3 algorithm as 4.46, with a standard deviation of 0.131 and a standard error mean of 0.019. On the other hand, the existing GPEN algorithm had a mean NIQE score of 7.22, with a standard deviation of 0.072 and a standard error mean of 0.010. These results indicate that while the NGAN3 algorithm had a slightly higher average NIQE score compared to GPEN, it also exhibited a higher level of variability in its NIQE score [18]. The standard error mean values

suggest that these estimates are based on a sample size of 20 observations for each group.

Table 132.2 presents the outcome of an independent samples t-test that compared the NIQE score of the proposed NGAN3 algorithm and the existing GPEN algorithm. The t-test revealed a significant difference in the mean NIQE score between the two algorithms, with a one-tailed p-value of 0.000 and a two-tailed p-value of 0.000. The table also includes various comparisons of the equality of means between the two algorithms.

Figure 132.1 depicts a bar chart that compares the mean NIQE score of the proposed NGAN3 algorithm and the existing GPEN algorithm. The chart displays the mean NIQE score of NGAN3 as 4.46, with a standard deviation of 0.131, and the mean NIQE score of GPEN as 7.22, with a standard deviation of 0.072. The standard error mean of NGAN3 is 0.019, and the standard error mean of GPEN is 0.010. The X-axis of the chart lists the two algorithms, while the Y-axis represents the NIQE score values. Error bars are included in the chart to indicate the confidence intervals at a 95% level, along with standard deviation displayed with a multiplier of 1.

Figure 132.2 illustrates the functioning of the proposed Novel Generative Adversarial Network v3, which takes sample low-quality (LQ) images as input provided by the user and produces high-quality (HQ) output images along with image quality scores using the NGAN3 algorithm.

4. Discussion

Based on the proposed algorithm considering four similar articles, the article author implemented a CGAN method for restoring underwater images performs better than existing methods in both the visual image quality and numerical measures of the restored images. The article author proposed the GAN model has been trained using a large number of real-world images and employs simple, practical modifications to the reconstruction process to ensure that the reconstructed images remain within the space of natural, high-quality images. The article author suggests a new approach for addressing issues related to rain removal from images, using a two-part network that combines a physics based model with a depth guided GAN for refinement. This method has been compared to other state-of-the-art techniques, and the experiments show that it performs better on real rain images, producing clear and detailed results. It has been shown to be effective at restoring high-resolution pictures from noisy low-resolution input, making it a useful tool for improving the resolution of CT images. The article author proposed a survey that provides an overview of GAN inversion, a technique that involves using pretrained GAN models to manipulate and restore images.

The proposed algorithm is designed to improve the restoration of blind face images by utilizing a rich, diverse generative model of facial images as a prior to provide high-quality images. Comparisons with other methods have shown that the proposed algorithm performs better for jointly restoring and enhancing faces in real-world images. The proposed NGAN3 algorithm has some limitations when it comes to restoring heavily degraded real-world images, as it can produce distorted facial details and unnatural results for extreme poses. As an outcome, using real data to learn the distributions instead of synthetic data could be a good direction for future based work.

5. Conclusion

Both algorithms were evaluated and compared with the proposed NGAN3 algorithm had a mean NIQE score of 4.46, while the existing algorithm had a mean NIQE score of 7.22. It is worth noting that in this case, a lower value represents higher performance. The NGAN3 algorithm was found to produce more realistic and high-quality images compared to the existing algorithm and also may provide well-paid jobs.

133 Improving execution rate in cloud task scheduling using Novel Hybrid Genetic algorithm over optimization scheduling algorithm

P. Sushma Priya[1,a] and S. John Justin Thangaraj[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Technical and Medical Sciences, Saveetha University, Chennai, India
[2]Research Guide, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Technical and Medical Sciences, Saveetha University, Chennai, India

Abstract: To improve the execution rate in cloud task scheduling using novel hybrid genetic algorithm over optimization scheduling techniques. An algorithm for scheduling tasks and a subset of cloud commuting are Novel hybrid genetic algorithms. The provision of various services over the internet, which uses tools and programs such as servers, databases, networking, and software as well as data storage. Materials and Methods: The data set needed for Task scheduling is acquired from the cloud sim tool. A platform for simulating and modeling cloud computing infrastructures and services is called Cloudsim. Novel Hybrid Genetic Algorithm and Optimization Scheduling Techniques are tested after importing the data sets. Two distinct algorithms were evaluated, resulting in the formation of two separate groups. Each group consisted of 120 samples, with a statistical power (G power) of 80%, a significance threshold of 0.05%, and a confidence interval (CI) of 95%. Results: The results were generated using the IBM SPSS software for the provided input data. According to the findings, the independent sample t-test revealed a highly significant difference with a p-value of 0.000 ($p<0.05$) between the two algorithms. The Novel Hybrid Genetic Algorithm exhibited a significantly higher execution rate compared to optimization scheduling techniques. Conclusion: Based on the findings, it can be established that the Novel Hybrid Genetic Algorithm achieved an execution rate of 105.0 MB/SEC, surpassing the Optimized Scheduling Algorithm's performance of 52.50 MB/SEC.

Keywords: Cloud computing, cloud sim, execution rate, novel hybrid genetic algorithm, optimization scheduling techniques, grid sim, sustainable

1. Introduction

The algorithms used are token routing, Round Robin, Randomized Central queuing, and least connection and they have explained how efficiently the system works when it is compared with the other Optimization scheduling techniques [1]. This article delves into the efficacy of cloud computing and the scheduling of cloud resources. It focuses on research regarding the optimization of task scheduling for software within a cloud computing environment, employing genetic algorithms [2]. The proposed algorithm presented in this article introduces a practical approach and methodology for task scheduling in a cloud computing setting [3]. Additionally, it efficiently enhances task scheduling effectiveness and maximizes the utilization of cloud computing resources [4]. The article provides insights into the utilization of cloud resources and the calculation of improved execution rates [5]. One of the key developments in the IOMT stage is cloud scheduling, which has an impact on how the cloud resource is used throughout its whole execution [12]. The creation of novel optimization scheduling algorithms that can manage complicated and dynamic workloads

represents one potential research need in this field. It is difficult to allocate resources efficiently in cloud computing systems because of the unpredictable workloads they produce and how quickly they might change [6]. The study introduces a novel hybrid genetic algorithm aimed at enhancing execution rates in comparison to existing task scheduling algorithms [7].

2. Materials and Methods

The proposed research was carried out at the Saveetha Institute of Medical and Technical Sciences, specifically at the Cloud Computing Lab within the Department of Computer Science and Engineering, located in Chennai [8]. The preliminary analysis involved conducting pretests for two algorithms while keeping the statistical parameters consistent, including a G power of 80%, a significance threshold of 0.05%, and a confidence interval of 95% [4].

The research involved two distinct groups, with each group comprising 120 samples, totaling 240 samples overall [9]. The significance levels used were alpha=0.05 and beta=0.2. The testing setup used is an Eclipse IDE for Java development. This version is 26.0 point one and a laptop with a configuration of 8GB RAM and with Intel Gen I5 processor and a 4GB graphics card [10]. Any type of data can be used, including docs, images, videos. CloudSim allows the description and simulation of various entities involved in parallel and distributed computing systems, including users, applications, resources, and resource brokers like schedulers [11]. This capability facilitates the development of scheduling algorithms [20].

2.1. Novel hybrid genetic algorithm

A general population improvement method based on a natural development pattern is the Novel hybrid genetic algorithm [12]. Each chromosome in genetic algorithms offers a potential resolution to a problem and is constructed from a series of characters [13].

Step 1: Choose a hybridization strategy
Step 2: Implement the genetic algorithm
Step 3: The heritage algorithm will be used to solve encoding and decoding [14].

Step 4: Selection of Fitness Function.
Step 5: Cross operation between the two individual algorithms.
Step 6: The genetic algorithm is submitted to a single mutation operation.
Step 7: Convergence Conditions [15].

2.2. Optimization scheduling techniques

First Come First Serve, Shortest Job First, Particle Swarm Optimization and Round Robin are called Optimization Scheduling Techniques.

Step 1: Download the data set into the cloud environment.
Step 2: Extract the packages.
Step 3: Now add the optimized scheduling tasks to the cloudsim.
Step 4: Add the resources and tasks to the cloud
Step 5: Perform the different tasks
Step 6: Calculate results obtained from the different types of scheduling techniques.
Step 7: Compare results of the optimized scheduling algorithms.

2.3. Statistical analysis

Statistical analysis was performed using IBM SPSS version 26.0.1, a software application commonly used for data analysis [16]. The datasets were first normalized, converting the data into arrays. Subsequently, the necessary number of clusters was determined and examined, and suitable algorithms were identified [17]. It is found that the Novel hybrid genetic algorithm's execution speed depends on the size of the work and the cloud environment [18]. The independent variables in the data sets are Optimized Scheduling techniques, Task size and the dependent variable in the data is execution rate. The independent T-Test used to analyze research [19].

3. Results

Tables 133.1 and 133.2 present the outcomes of the Novel Hybrid Genetic Algorithm (HGA) and Optimization Scheduling Techniques algorithms.

Table 133.1. Number of epochs taken for the HGA and Optimization scheduling Algorithms are 20. Mean value for Group 1 is 105.0000 and Group 2 is 52.5000

	Algorithms	N (Number of Epochs)	Mean	Standard Deviation	Standard Mean Error
Execution Rate (MB/SEC)	HGA	10	105.0000	30.27650	9.57427
Execution Rate (MB/SEC)	Optimized scheduling techniques	10	52.5000	15.13825	4.78714

Source: Author.

Table 133.2. The independent sample T-Test was conducted on the dataset with a 95% confidence interval, revealing that the Novel Hybrid Genetic Algorithm exhibits superior performance compared to the Optimized Scheduling Techniques. The significance level obtained from the independent sample t-test was 0.000 (p<0.05)

		Levene's test for equality of variables		T test for equality of means					95% confidence interval of the difference	
		F	sig	t	df	Sig (2-tailed)	Mean Difference	Std. error Difference	Lower	Upper
Execution Rate	Equal variances assumed.	5.625	.030	4.905	18	.000	52.50000	10.70436	30.01097	74.98903
Execution Rate	Equal variances not assumed.			4.905	13.235	.000	52.50000	10.70436	29.41636	75.58364

Source: Author.
Figure 133.1. Barchart showing the comparison of mean execution and standard errors for Novel Hybrid Genetic Algorithm. Novel Hybrid Genetic Algorithm is better than Optimization scheduling Techniques in terms of execution rate and standard deviation. X-Axis: Novel Hybrid Genetic Algorithm vs Optimized Scheduling Techniques Y-Axis: Mean Execution Rate ± 2 SD.

Source: Author.

Table 133.1 shows the group of statistical results performed on all iteration variables. The Novel Hybrid Genetic Algorithm has shown better performance than the Optimized Scheduling techniques. The standard deviation of Novel Hybrid Genetic Algorithm is 30.27650 and 15.13825 for optimized scheduling algorithms. Standard error mean of Novel hybrid genetic algorithms is 9.57427 and 4.78714. For optimized scheduling techniques, the results of your sample random test are displayed in Table 133.2. The confidence intervals are set to 95% for the data set using the independent sample T test. Novel Hybrid genetic algorithm performs better than the optimized scheduling techniques in this the difference execution rate between Novel hybrid genetic algorithm and optimize scheduling algorithm has shown. The T test for equality means has shown a similar mean difference 52.5 and similar standard deviation difference. The 95% confidence interval has shown 30.01097 for the optimized scheduling technique. The results of the independent sample t-test indicate a significant difference, with a p-value of 0.000 (p<0.05), highlighting the presence of a statistically significant distinction between the two algorithms. Notably, the Novel Hybrid Genetic Algorithm exhibits a superior execution rate compared to Optimization Scheduling Techniques.

Figure 133.1 illustrates a bar chart depicting the Execution Rate of the two algorithms across various sample sizes. The x-axis represents the algorithms, while the y-axis represents the Execution Rate. The bar chart unmistakably demonstrates that the Novel HGA outperforms Optimization Scheduling Techniques in terms of Execution Rate [20].

4. Discussion

In cloud computing, grid sim can be used to simulate and evaluate the performance of cloud computing systems. Sustainable cloud computing requires a holistic approach that considers the entire lifecycle of computing resources, from their production to their disposal. By adopting sustainable practices, cloud providers and users can help reduce the environmental impact of cloud computing and contribute to a more sustainable future. The quantity and pattern of virtual machines from the cloud are finally processed in this way. Numerous scholars have explored the efficacy of resource scheduling algorithms within grid environments to evaluate their applicability in cloud computing. Within the context of cloud computing, certain studies present an approach grounded in evolutionary algorithms. This algorithm's efficiency is demonstrated when considering scheduling time, scheduling costs, and task scheduling for system resources in cloud computing consumption. It offers a practical concept and strategy for task scheduling in cloud computing, optimizing job scheduling efficiency and resource utilization. In the future, the adoption of multi-policy cloud resource scheduling, in conjunction with dynamic task scheduling in the cloud, will be explored. This will involve the integration of various cloud resource

scheduling policies and algorithms to ensure a balanced distribution of resource workloads.

5. Conclusion

In this article, the research says that the Hybrid Genetic Algorithm (105.0000 MB/SEC) has a higher Execution Rate than the Optimized Scheduling Algorithm (52.5000 MB/SEC). According to experimental findings, enhanced genetic algorithms are more effective at scheduling cloud resources, attaining more reasonable task scheduling, and providing perfect task scheduling outcomes.

Abstract: The aim of this research is to detect speed bumps from a given image using Otsu's threshold for better detection accuracy. The total sample size of 120 has been split into two different groups. The first group holds 60 samples and was tested on Adaptive Gaussian Threshold whereas the next group holds 60 samples and was tested with Otsu's Threshold. The sample size for each group is 10. The research's dataset was downloaded from Kaggle.com and consists of 6000 photos, of which 4800 are utilised for training and the remaining ones for testing. The G power for this project is approximately around 80%. The resultant accuracy is higher for the Otsu's Threshold (88.40%) than that of Adaptive Gaussian Threshold (85.60%). The achieved significance value is 0.002 ($p < 0.05$) which shows that there is statistical significance between the two algorithms considered for the speed bump detection. Various approaches for detecting speed bumps are discussed in this paper and compared with the existing models. The research work concludes that the accuracy of Otsu's Threshold is higher than Adaptive Gaussian Threshold with an accuracy percentage of 88% and 85% respectively.

Keywords: Adaptive threshold, Otsu's threshold, Gaussian threshold, roads, image processing, novel speed bump detection, intelligent vehicle system

1. Introduction

When using adaptive thresholding, the weights are a gaussian window, and the threshold value is equal to the sum of the neighborhood values. The mechanism for regulating traffic on the roads is seen to be utterly ineffective without speed bumps [1]. In order to slow down traffic and improve neighborhood safety, speed bumps are made and installed on roads. The project's most promising use is to make driving safer and prevent accidents caused by speed bumps that go unseen [2]. On adequately painted highways, speed bumps are identified using Gaussian filtering, median filtering, and connected component analysis to improve the Advanced Driver Assistance System [6, 14, 15]. This approach is used without the expense of any specialized sensors or GPS [6]. After studying various papers on novel speed bump detection, the paper was fascinating and used image processing techniques to recognize the speed bump with the help of gyro and sensors [4]. The lack of precision in speed bump recognition from distant photos and occasionally incorrect speed bump detection in the images represent a research gap in this area [3]. The current methods are found to take a substantial amount of time to inform the drivers and to have lower accuracy when identifying speed bumps [4]. The main objective of the research work is to contrast two alternative algorithms namely Otsu's Threshold and Adaptive Gaussian Thresholding and show that Otsu's gives better accuracy on speed bump detection.

2. Materials and Methods

The Department of Artificial Intelligence Laboratory at the Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, is where the project's research was conducted [5]. In this particular research article, there are two groups. These two are called Otsu's Threshold and Adaptive Gaussian Threshold, and they differ in terms of how accurately they can identify speed bumps in images [6]. There are 120 samples in all, which are equally split between the two groups. The first group receives the accuracy of the first 60 samples, while the second group receives the accuracy of the remaining 60 samples [1]. The number of iteration executed for each group is 10. The dataset for the research has been downloaded from Kaggle.com which contains 6000 images where 4800 images are used for training and the rest for testing [7]. The number of sample sizes is calculated using past research attempts [6], a confidence interval of 95%, a 0.05 threshold of significance, and an 80% G-power.

To run the framework for the research, it requires a minimum of 4GB of RAM for easy access to the processor [8]. In terms of processor, for the research work Intel(R)CPU @ 1.10GHz and above is recommended. As far as Operating System is considered, and used Windows 11. To save all the images of the data set that are collected and downloaded from the internet, to store the code, and to install the necessary plugins to aid the code, the system needs a storage space of 30GB. The framework is run in Jupyter Notebook, and the software is tested with photos of speed bumps [9].

2.1. Otsu's threshold

Otsu's method is a type of adaptive thresholding used for binarization in Image Processing. The method, in its most basic form, outputs a single intensity threshold that divides pixels into the foreground and background classes [10]. By considering every feasible threshold value, it may determine the input image's ideal threshold value (from 0 to 255). The technique analyzes the image histogram and segments the items by minimizing the variance for each class [11]. This method typically yields the correct outcomes for bimodal data. Two distinct peaks can be seen in the histogram of such an image, each of which represents various ranges of intensity values [12].

Otsu's Threshold Algorithm steps:

Step 1: The images are preprocessed after being imported from the dataset. To prepare images for the procedure computationally, preprocessing is applied to the images.

Step 2: All of the input images are resized during preprocessing to the presumptive size of 200*350. The

undesirable areas of the input photographs will be removed through resizing.

Step 3: After scaling, luminosity methods are used to turn the RGB color images into grayscale versions. To lessen the complexity caused by computing needs, color conversion is used.

Step 4: Applying Otsu's Threshold algorithm to the grayscale image and converting them into a Binary image.

Step 5: Calculate the image histogram for the input image. Decide on a threshold value, then calculate the foreground and background variances.

Step 6: The threshold value (T) is generated. According to the grayscale pixel value, it is assigned as black and white.

Step 7: The bounding boxes indicate that a speed bump has been spotted in the given input image.

2.2. Adaptive threshold Gaussian

Adaptive thresholding is a part of Image Binarization and it has two methods of approach, Adaptive threshold mean and Adaptive threshold gaussian. Adaptive thresholding is used to separate the desired object from the background image based on various pixel intensities in each region of the image [13]. In adaptive thresholding, the threshold value is automatically selected in accordance with the image pixels and layout in order to transform the image pixels to grayscale or a binary image rather than being manually specified or subject to any limits [16]. This approach facilitates the automated selection of the threshold value to distinguish the primary item from its background when there are variations in lighting, color, or contrast in the image [14].

Adaptive Threshold- Gaussian algorithm steps:

Step 1: Preprocessing is done to the images after they are imported from the dataset. To prepare images for the procedure computationally, preprocessing is performed to the images.

Step 2: All of the input images are resized during preprocessing to the presumptive size of 200*350. The unwanted portions of the input images will be removed by resizing.

Step 3: After scaling, luminosity techniques are used to turn the RGB colour images into grayscale versions. To lessen the complexity caused by computing constraints, colour conversion is done.

Step 4: Applying the Novel Adaptive Threshold Gaussian algorithm to the grayscale image and converting them into a Binary image.

Step 5: The Haar Cascade classifier used in the speed bump detection framework was trained and developed using a variety of speed bump images.

Step 6: The detected speed bumps are highlighted with the bounding boxes mentioning that a speed bump has been detected.

2.3. Statistical analysis

The resultant statistical analysis was obtained using IBM SPSS version 29. An independent sample t-test has been run for the analysis to compare the mean accuracies [15]. The correlation table is created in SPSS using bivariate correlation [9]. There is no dependent variable in the research; the independent variables are accuracy and the number of input photos. The sample size considered for the research is (N=10) and the significance value is 0.002 [16].

Table 134.1. Consists of accuracies of a sample size of 10 for both Otsu's Threshold (OT) algorithm and Adaptive Threshold- Gaussian (ATG) algorithm

S. No	OT	ATG

3. Results

The Jupyter notebook tool is used to execute the suggested algorithms Otsu's Threshold and Adaptive Threshold Gaussian several times [17]. Otsu's Threshold method in Group 1 provided accuracy of 88.40%, and Adaptive Threshold Gaussian algorithm in Group 2 provided accuracy of 85.60%. As a result, Otsu's Threshold performs better than Adaptive Threshold Gaussian method.

The values of the calculated accuracy for the Otsu's Threshold method and for the Adaptive Threshold Gaussian algorithm are shown in Table 134.1.

For both Otsu's Threshold and Adaptive Threshold Gaussian algorithms, the values of the mean accuracy and the values of standard deviation are shown in Table 134.2. The mean accuracy for the Otsu's approach is 88.40, while the mean accuracy for the Adaptive Threshold Gaussain is 85.60.

The sample size for independent t-tests comparing the Otsu's Threshold and Adaptive Threshold Gaussian methods is shown in Table 134.3. For Otsu's Threshold and Adaptive Threshold Gaussian algorithms, the analysis is carried out by showing the values in form a graph [18].

Figure 134.1 shows the results of the Novel Otsu's Threshold and the Adaptive Gaussian Threshold. Novel Otsu's Threshold can identify the entire speed bump in a plain backdrop whereas Adaptive Gaussian Threshold can only detect a portion of the speed bump.

Table 134.2. Group statistics which shows a sample size of N=10 for each group. The mean percentage of Otsu's threshold algorithm is 88.40% whereas the accuracy percentage of the Adaptive Gaussian Threshold algorithm is 85.60%. Standard deviation, as well as the standard error rate, is also shown

	Groups	N	Mean	Std. Deviation	Std. Error Rate
Accuracy	OT	10	88.40	2.31900	0.73333
	ATG	10	85.60	2.91357	0.92135

Source: Author.

Table 134.3. The independent sample t-test and the equal variance assumed is compared with equal variances in the accuracy with confidence interval of 95% (statistically significant (p<0.05))

		Levene's test for equality of variances		T-test for equality of means					95% Confidence Interval of the Difference	
		F	Sig.	t	df	Sig. (2-tailed)	Mean difference	Std. Error difference	Lower	Upper

Output-Adaptive Gaussian Threshold   Output-Novel Otsu's Threshold

Figure 134.1. The figure (left) represents the output of Adaptive Gaussian Threshold and the figure (Right) shows the output of Novel Otsu's Threshold.

Source: Author.
Figure 134.2. Bar chart which compares the mean accuracies of both the existing and proposed algorithm. The accuracy is taken on the Y-axis while the proposed and the existing algorithm is taken on X-axis. The accuracy of Otsu's Threshold algorithm is 88.40 % and the Adaptive Gaussian Threshold algorithm is 85.60 %. The mean accuracy detection is ± 2SD.

Source: Author.

The mean accuracy comparison between the Adaptive Threshold Gaussian method and the Otsu's Threshold algorithm is shown graphically in Figure 134.2. The final results demonstrate that the Otsu's Threshold method exceeds the Adaptive Threshold Gaussian in terms of performance.

The mean accuracy detection is +/-2SD.

4. Discussion

The accuracy percentage obtained for Otsu's Threshold threshold algorithm is 88% and the accuracy percentage obtained for Adaptive Gaussian Threshold algorithm is 85% respectively. Otsu's threshold algorithm has been used in various research findings such as for edge detection, face detection, motion detection, and content recognition. Adaptive Gaussian Threshold is appropriate for detecting speed bumps because it converts RGB image to grayscale image for more accurate detection. For detecting marked speed bumps, stereo

vision is a unique method applied to local binary pattern images [3], anyway the results obtained are not quite accurate in the detection. The research is limited by the fact that when an image is taken in low light, it is difficult to detect speed bumps accurately. In addition, when an unmarked speed bump is provided as input, the novel speed bump detection accuracy is noticeably low. One aspect that distinguishes the speed bump from the crosswalk is its elevation. However, in other images the elevation is not clearly defined, making it difficult to find. The future scope of novel speed bump detection is to detect speed bumps which can be marked or unmarked in a real time video. Better DNN techniques can be used for more accurate detection of the speed bump on roads with the development in technique.

5. Conclusion

The research work concludes that Ostu's Threshold algorithm which has an accuracy of 88.40% performed better than the Adaptive Gaussian Threshold algorithm with an accuracy of 85.60%. Thus, the use of Otsu's Threshold algorithm in novel speed bump detection gives significantly better accuracy than the Adaptive Gaussian Threshold algorithm. The suggested working model increases accuracy by being trained with additional images that were taken from diverse perspectives and under varying lighting conditions especially Night time.

Abstract: The objective of the research is to compare the performance of a Recurrent Neural Network method and a Linear Discriminant Analysis technique for automatic face mask detection to find whether a person is wearing a mask or not. In this study, there were two groups with sample size of 100 which were iterated 10 times. The accuracy, performance of the Recurrent Neural Network Classified. Linear Discriminant Analysis and Recurrent Neural Network Analysis are tested by using ClinCalc with a G power of 0.8 with 95% confidence interval. The identification dataset was taken from Kaggle and consists of 20,981 images of 120 face masks. To classify each image using RNN and LDA, 224 rows and 224 columns are used. The outcomes demonstrate that the Novel Recurrent Neural Network has a substantially greater accuracy (94.9%). Recurrent neural networks and Principal Component Analysis shows that it is statistically significant, with (p=0.017) (p<0.05). Linear Discriminant Analysis method is less accurate on average in face mask detection than Novel Recurrent Neural Network.

Keywords: Novel recurrent neural network, linear discriminant analysis, covid-19, face mask, society, technology

1. Introduction

It can help promote public health by ensuring that individuals follow mask-wearing guidelines, reducing the risk of disease transmission [1]. Automatic face mask detection is a cutting-edge technology that uses computer vision and artificial intelligence algorithms to detect the presence of face masks on individuals in real-time. With the ongoing global health pandemic, the use of face masks has become a crucial measure to prevent the spread of respiratory diseases, including COVID-19 [15, 16]. Governments continue to use face mask detection as a tool to help promote public health and safety. Comparative face mask detection can limit the spread of COVID-19 [2]. In this article face mask detection technology has become a common feature in society as a means of enforcing mask-wearing policies and reducing the spread of infectious diseases such as COVID-19. Face mask detection using a smart city network was implemented for the whole city to ensure that every person in the society follows the rules [3]. The use of face mask detection technology has become increasingly prevalent in society, as it is seen as an effective tool to enforce mask-wearing policies and reduce the spread of infectious diseases like COVID-19. While the use of face mask detection technology has raised concerns about privacy and potential misuse, many organizations and governments continue to use it as a means to promote public health and safety for society. This study is to improve accuracy of face detection algorithms with face masks. The aim of work is to identify masks of a Person by face detection using Deep Learning Techniques.

2. Materials and Methods

The Sample size for each iteration is 10 (Group 1=10, Group 2=10) by keeping G power 80%, confidence

---

[a]mariasanchetti238@gmail.com

interval 95%. This dataset is downloaded from the Kaggle website [14]. This dataset has Gpu, Dataset of images, a framework, and a programming environment. In the testing set for the recommended method to adopt for statistical analysis, the Jupyter Notebook and SPSS programme were used [4].

The HP Pavilion AMD Ryzen 5 4600H with Radeon Graphics 3.00 GHz, 8GB RAM, Ryzen 5 11th gen processor, 512 GB storage, and Windows 11 operating system served as the testing platform for the proposed job [5]. The facial mask employing Recurrent Neural Network data set, which is open source and was downloaded from kaggle, was employed in this research project. Numerous images of different people's faces can be found in this dataset. There are 182 images in the collection, which is 59.7 MB in size. Train and Test were the two segments of the dataset. The test dataset only has 30 pictures, while the train dataset has 124 pictures. This face mask detection was extracted from the .csv file, which was saved [6].

2.1. Linear discriminant analysis

Linear Discriminant Analysis (LDA) is a supervised learning algorithm used for classification and dimensionality reduction. In LDA, the goal is to find a linear combination of features that maximizes the separation between two or more classes. This is done by computing the mean and covariance matrix of each class, and then finding the direction (i.e., the linear discriminant) that maximizes the ratio of the between-class variance to the within-class variance [7]. Once the linear discriminant is found, it can be used to project the data onto a lower-dimensional space, while preserving the class separability [8]. This can be useful for visualizing high-dimensional data or for reducing the dimensionality of the data before feeding it to a classification algorithm LDA assumes that the data is normally distributed, and that the classes have equal covariance matrices. LDA is a popular and widely used algorithm in fields such as image recognition, bioinformatics, and finance, among others [9].

Algorithm
    Step 1: Loading the data set of initial stage
    Step 2: Obtaining noise free facial regions
    Step 3: Processing of feature extraction using noise removed data
    Step 4: Detection of face mask has to be done

2.2. Recurrent neural network algorithm

Recurrent neural networks are a particular kind of neural networks that are particularly good at handling sequential data, like time series or text that is written in natural language [10]. Since RNNs have the ability to "remember" previous inputs by conveying hidden

states from one time step to the next, they are especially useful for applications like language modeling, machine translation, and audio recognition. RNNs are recurrent layers that are applied at every time step of the input sequence [11]. Each layer also inputs an input vector and a hidden state vector from the previous time step, along with a new hidden state vector and an output vector. In contrast to the output vector, which is frequently used for prediction or classification, the hidden state is carried over to the next task [12].

Algorithm:
    Step 1: Data is gathered as input set of face mask photographs on a global website.
    Step 2: Pre-processing is carried out in this stage.
    Step 3: Following that, image post-processing will happen.
    Step 4: Processing of the suggested algorithm occurs.
    Step 5: To find the face mask, the pre-processed photos are put to use.
    Step 6: In this stage, the face mask of a person is accurately recognised, and the time required by the chosen algorithm is visualized.

2.3. Statistical analysis

This study compared the mean accuracies of the two methods using IBM's SPSS (Version 26) software for statistical analysis [13]. Lighting settings, camera angle, mask type, and environmental influences are independent variables [14]. Datasets are prepared using 10 as the sample size for both the algorithm RNN and LCD. The Novel Recurrent Neural Network's precision for each approach is assessed using a different T-test analysis. The variable that is being measured or observed in

an experiment that is anticipated to change as a result of the independent variable is known as the dependent variable [4]. The dependent variables Crowd density, Mask Fit, Mask Type Classification, and Binary Classification [15]. The dependent variable is Accuracy, while the independent variables are the person's individual characteristics, such as skin tone, age, and gender.

3. Results

Table 135.1 by varying the number of records in the training dataset (94%), and the testing dataset (86%),

as well as how the results are displayed, the RNN and LCA algorithms are compared with 10 samples [16].

Table 135.2 indicates the mean accuracy of the novel recurrent neural network algorithm, which is superior to the linear discriminant analysis approach with standard deviations of 98241 and 2.26847, respectively.

Table 135.3 reflects the T-test comparison of the novel recurrent neural network algorithm and the linear discriminant analysis [17]. A T test with an independent variable was performed between the study groups to determine the mean, standard deviation, and standard error mean [18]. Where ($p<0.05$), the significance value between two algorithms is 0.017.

Figure 135.1 shows an independent t sample Test for algorithms. The comparative accuracy analysis and mean of loss between the two algorithms are specified. The comparison of the mean accuracy of the Deep learning that is Recurrent Neural Network and Linear Discriminant Analysis algorithm shown in Figure 135.1.

4. Discussion

In the study mentioned above, the Novel Recurrent Neural Network scored 95. 4% accuracy for face mask detection compared to the Linear Discriminant Analysis algorithm's 85 [19]. The results showed that the recurrent neural network algorithm worked better when there was more training data, and technology has advanced significantly since then [20]. Recent research found that the proposed with a 0. 72 root mean square value, demonstrated that the innovative Linear Discriminant Analysis technique is a suitable choice for face mask detection based on historical data, a novel Recurrent neural network model was presented for various

financial organizations, and it was discovered that the error level significance decreases as the data is kept for extended periods of time. The new Linear Discriminant Analysis network approach compares the movement of the face mask in various sectors to detect face masks. Even though there are not many papers that describe the drawbacks of suggested LDA techniques [21]. The performance of the proposed face mask detection system is measured and compared to other existing systems in terms of error rate, inference time, correlation coefficient, data over-fitting analysis, precision, and recall. In order to assess whether a person is wearing a mask or not, face mask detection systems use computer vision algorithms. Some of the main limitations of face mask detection systems are: Partially worn masks, Lighting conductions, obstructed view, Diversity of masks.

5. Conclusion

The main objective of this project is to get the awareness in people that wearing the mask. The Novel recurrent neural network has the higher accuracy of 94.9% compared to the which only has an Linear Discriminant Analysis 86.2%. So, the Novel recurrent neural network appears to be significantly better than Linear Discriminant Analysis for predicting the results in the face mask detection. Hence this is very useful to society. This is mostly used in covid-19 times.

Abstract: The aim of this study is to improve the accuracy in finding out the forgery analysis using the Novel MultiLayer Perceptron against Random Forest Algorithm. Novel MultiLayer Perceptron and Random Forest Algorithms are classifier algorithms under machine learning. The two algorithms in this study are Novel MultiLayer Perceptron and Random Forest Algorithm. A sample size of 10 is used for each group and the parameters of the present study include the values alpha and beta with 0.05 and 0.2 by setting the G power at 80%. In defining the forgery analysis with significance value, the Novel MultiLayer Perceptron produces an accuracy 84.2%, which is more accurate than the Random Forest Algorithm with accuracy value 77.4% and the significance value for these two algorithms are 0.012 ($p<0.05$) which shows that there is statistically significant difference between the two groups. The Novel MultiLayer Perceptron is 6.8% more accurate than the Random Forest Algorithm in classifying forgeries. This algorithm gives the best result.

Keywords: Classifier, energy efficiency, forgery analysis, fake data, machine learning, novel multilayer perceptron, random forest algorithm

1. Introduction

In earlier days, people used to purchase their products through offline methods and there were no online methods recently. They used to buy their product on the buying place itself with the other customer reviews who were standing beside them. As technology is increasing or growing day by day, people's power is becoming flawless nowadays [14]. By the help of people's weakness, the marketing is flattering and current online products are trending into the real world. Not only the pros for delivering online products to the end users of energy efficiency, here cons are also marked. The crucial major feature is that it will be helpful for measuring products from different localities in one online shopping, which reduces the work, provides opinion from a number of individuals and many things to be added, as well as cons. But the major area of the research is about online fake data [6]. As people will shop according to their needs and will buy through online and save their time but by buying through online many people will follow the reviews of the product and go to the next step of billing. The key role of every human psychology is reviews or feedback from different individuals for a particular product [5]. This is also another platform for the hackers to change the clarity of the product, with the fake data reviews they may increase the level of the product or they can decrease the status of the consequence. So by finding fake data reviews using different machine learning algorithms and finding whether the review which is given by the human is fake data or

[a]anirudhsmartgenresearch@gmail.com

genuine [13]. Manipulation Behavior is one of the major technique for a human to manipulate the people easily to buy a particular product. Forgery analysis is used in many different areas, not only in particular online methods, there are many frauds like fingerprint scanning, fake data news, fake data documents and many others. These many areas come under forgery analysis.

There are 36 articles related to this research in IEEE Xplore standards and 19 in Scopus. Novel Multilayer Perceptron is derived from structured data algorithms [6, 13]. The observation of forgery analysis using machine learning was performed. Analysis of reviewing of product applications techniques for classification models were evolved and this article includes about the manipulation behavior of the peoples [12]. This first Report was developed based on forgery analysis using machine learning techniques. Automatic finding of forgery analysis was derived with different algorithms with finding of higher accuracy of energy efficiency, as study says my finding shows that fraudulent reviews typically have lengthier sentences, more pauses and duplicate phrases. The most cited article is based on forgery detection [1–3, 17]. Using these language variables, it is able to distinguish false reviews from actual reviews with great accuracy. The overall best cited article is Forgery Analysis using Machine Learning Techniques [3, 17]. As many datasets contain 1000 of datasets but to detect which is genuine dataset regarding the algorithm and finding of higher accuracy comes to final discussion of the article [9]. Energy Efficiency comes under a factor called accuracy output, this states that less energy efficiency is required to complete a task or achieve the same outcome.

The disadvantage or the trouble is that finding out which data is genuine or fake is extremely difficult to find because the majority of currently used standard feature extraction procedures are created for quick analysis [16, 18]. The aim of this article is to improve the accuracy gain for figuring out the forgery issues with greater accuracy and with different methodologies with low complexity.

2. Materials and Methods

The research work is carried out in the Machine Learning Lab at Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Chennai. Two numbers of groups are selected for comparing the process in forgery analysis and their results. In each group, 10 sets of samples and 20 samples in total are selected for this work [14]. The Random Forest Algorithm and Novel MultiLayer Perceptron methods are two techniques of machine learning algorithms that are used. Both of these methods are a part of the classifier. The research uses two samples of groups of which Group 1 is Novel Multilayer Perceptron and which is contrasted with Group 2 Random Forest Algorithm. With an accuracy output, it is iterated 10 times to

obtain increased accuracy with G-power 80%, threshold 0.05%, and Confidence Interval (CI) 95%.

Kaggle is an open source software tool and the dataset is extracted from Kaggle. The dataset consists of 7000 rows and 10 columns, language used for the code is python programming which is executed in google colaboratory. The dataset contains the attributes and its values [7]. The dataset is about Forgery Analysis detection. The current dataset consists of 10 columns and 7000 rows and some of the column names are:

Customer ID
- Customer Name
- Customer Address
- Customer Feedback
- Product ID

There are options for both hardware and software settings in the testing setup. The laptop has a hard drive, of SSD and Intel Core-based processor of i5 12th generation CPU, RAM 16GB and it is a 64-bit operating windows system. The software is currently a Python-programmed colaboratory and works with Windows 11. The accuracy value will be displayed after when the program is finished. Procedure is a laptop linked to Wifi. With aid of Google Collaborative tool is used to execute python code for present research. After that the program can be saved for further iterations. After getting an iteration of 10 accuracy values, save the file and keep the accuracy values in the SPSS tool to get the final result of the graphs and mean values.

2.1. Novel multilayer perceptron algorithm

Novel Multilayer Perceptron is an Machine Learning algorithm in which it is used for detection of forgery analysis to predict the future profits. Nowadays, forgery analysis is becoming an effect to the economy, so this article predicts the output.

Algorithm
    Input: Dataset K.
    Output: A testing dataset class
    Step 1: Choose an weight vector initially
    Step 2: start an approach for minimization
    Step 3: Apply the vector to the network and calculate the network output
    Step 4: Compute the average output
    Step 5: Calculate all the weights and update the sum from the initial stage

2.2. Random forest algorithm

Random Forest Algorithm is used here to forecast future gains, the forgery analysis. It significantly affects how the economy is predicted. Therefore, the program anticipates the forgery analysis.

Algorithm
    Input: Dataset K.

Output: A testing data class

Step 1: Randomly select K data points from the training set.

Step 2: Build decision trees using the chosen data points.

Step 3: Choose a number N to signify how many decision trees are planned to construct.

Step 4: Carry out steps 1 and 2 again.

Step 5: After identifying the new data points that each decision tree predicts, allocate the fresh data to the category that has earned the most support.

2.3. Statistical analysis

SPSS tool is used for calculating the t-test values. The accuracy values of colaboratory code is iterated 10 times with prediction of accuracy after every iteration which is analyzed, energy efficiency takes less complexity to complete a task. Independent samples are used to determine significance values between 2 groups, a t-test was conducted [4]. The factors used in forgery analysis are independent variables, whereas the forgery prediction is the dependent variable.

3. Results

The research has been taken among two machine learning algorithms, these two algorithms are classifier algorithms, one is called Novel MultiLayer Perceptron and Random Forest Algorithm.

The energy efficiency output of Novel MultiLayer Perceptron was the greatest among the group, with a mean accuracy of 84.2% and a standard deviation of 0.324, as shown in Table 136.1. RFA's accuracy is on average 77.4%, with a standard deviation of 0.237. The suggested RFA method performs better than the Novel MultiLayer Perceptron.

The results of the independent samples T-test for Novel MultiLayer Perceptron and RFA are shown in Table 136.2. The average difference is 6.8 and 0.127

Table 136.1. Group Statistics Results- Novel Multilayer Perceptron has an mean accuracy (84.2%), whereas for RFA has mean accuracy (77.4%)

	Algorithm	N	Mean	Std. Deviation	Std. Error Mean
Accuracy	NMLP	10	84.2530	.32486	.10273
	RFA	10	77.4030	.23786	.07522

Source: Author.

Table 136.2. Independent sample test for significance and standard error determination. P-value is less than 0.05 considered to be statistically significant and 95% confidence intervals were calculated

	Leven's Test for Equality of Variances		t-test for Equality of Mean			95% Confidence Interval of the Difference	
		F	Sig	Sig (two-tailed)	Mean Difference	Std. Error Difference	Lower	Upper
Accuracy	Equal Variance assumed	1.28	6.28	0.012	6.85	0.12732	5.18700	6.75245
	Equal Variance not assumed			0.012	6.85	0.12732	5.18862	6.75458

Source: Author.
Figure 136.1. Bar Graph represents the comparison of the mean gain for two algorithms obtained from SPSS software. All the mean values are loaded into the SPSS software to obtain t-test, independent samples bar chart representation. X-axis represents Groups and Y-axis represents Mean accuracy. The accuracy mean is considered as 95%CI and +/- 2SD.

Source: Author.

is the standard error of the difference. These results state that there is a statistically significant difference between these two groups namely Novel MultiLayer Perceptron and Random Forest Algorithm with significance value of 0.012.

The bar graph comparison between Novel MultiLayer Perceptron and Random Forest Algorithm is shown in Figure 136.1.

4. Discussion

The Novel MultiLayer Perceptron algorithm in this study has a forgery analysis detection accuracy value of 84.2%, which is more accurate than RFA's result, 77.4% accuracy rate. RFA also generates good findings with a low standard deviation. The significant value is 0.012 which is obtained using an independent sample t-test.

The accuracy of this article's equivalent results for forgery analysis, using a Novel MultiLayer Perceptron technique is 77.8%. The accuracy of the current work's Novel MultiLayer Perceptron, which is used to locate or identify forgeries in application reviews is reported to be 84.2%. The earlier research, which Yellapragada proposed in 2021, indicates that the Novel MultiLayer Perceptron has a 77.8% accuracy rate [4]. The Random Forest Technique, which has an accuracy range of 60% to 77.4% for the current study, is another algorithm that is utilized or compared to determine forgery detection [8]. A yelp dataset, which tends to provide accuracy, is currently employed to forecast accuracy. Generally speaking, many algorithms offer varying accuracy ranges based on various datasets and their use is expanding to make more accurate predictions [10, 11]. As RFA is a parameter that is used to quantify the forgery detection in both modern and conventional approaches to research on the specific article, RFA demonstrates less accuracy than Novel MultiLayer Perceptron when compared to other algorithms [15].

The factors which are affecting the research is, as the length of the dataset decreases, the value of accuracy is getting affected. The limitations of this research is that for smaller datasets, no appropriate output. The future scope for the current work is to predict the fake data and genuine reviews on applications based on classifier algorithms with less complexity and high accuracy.

5. Conclusion

The Novel MultiLayer Perceptron and Random Forest Algorithm were used in this study to detect counterfeit reviews on applications. The Novel MultiLayer Perceptron has an accuracy score of 84.2% whereas the RFA has a 77.4% accuracy score. Compared to Random Forest Algorithm, Novel MultiLayer Perceptron appears to be more accurate at spotting forgery detection. The Novel Multilayer Perceptron classifier outperformed the Random Forest Algorithm.

137 Determining the enhancement of fake reviews by comparing novel MultiLayer perceptron and gradient boosting algorithm in predicting forgery analysis in E-commerce application

D. V. Sudheshna Sai[1,a] and B. B. Beenarani[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Research Guide, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The intent of this research is to increase the accuracy in finding out the forgery analysis using two machine learning algorithms called Novel MultiLayer Perceptron over Gradient Boosting Algorithm. These two algorithms are classification algorithms. This article has two groups namely Novel MultiLayer Perceptron and Gradient Boosting Algorithm, Group 1 is called Novel MultiLayer Perceptron and Group 2 called Gradient Boosting Algorithm, each group has sample size 10. The parameters used are alpha 0.05, beta 0.02 and G-power value 80%. The output accuracy values for Novel MultiLayer Perceptron over Gradient Boosting Algorithm are 84.2% and 78.29%. The mean accuracy and standard deviation is 5.96, 0.11. The attained significance value is 0.017 ($p<0.05$) which states that there is statistically significant difference between these two algorithms. Finally, this can conclude that the Novel MultiLayer Perceptron is having a high accuracy of 3.6% over the Gradient Boosting Algorithm.

Keywords: Classification, forgery analysis, fake data, gradient boosting, machine learning, novel multilayer perceptron, trade

1. Introduction

Many of humans' daily activities have been influenced by the Internet's explosive rise. E Commerce is one of the trade sectors with the fastest development. Trade is a subset of the E-commerce factor. Nowadays trade and marketing is becoming a trend. The majority of e-commerce sites allow users to post reviews of their services and to reach every product to the customer. Through the trade system, it will help the customers to easily buy a product. The business people can trade their product into e-commerce applications. These reviews can be used as a source of knowledge. For instance, businesses can use it to select how to design their goods or services, and prospective customers can use it to choose whether to purchase or use a product [10]. Unfortunately, trade became possible because some people have tried to manufacture fake data reviews in an effort to either boost the popularity of the product or discredit it, taking advantage of its significance. This study uses the language and rating properties from reviews to identify fake data reviews [12]. For many people, especially potential buyers, reading product reviews before purchasing the item becomes a habit, the people frequently examine reviews of the current product from customers before making a purchase decision [13]. There is a good possibility that customers will purchase the product if the review is primarily positive but, if it is primarily

negative, usually choose another option. Although good customer feedback can result in substantial financial gains for organizations, it can also be considered when making decisions about how to create products and what services to offer consumers [3, 7, 15]. It has become a habit for many people, particularly prospective purchasers, to read product reviews before making a purchase. Before making a purchase, people will frequently read user reviews of the current product. If the reviews are mostly positive, there is a good chance that people will buy the product nevertheless, if the reviews are mostly negative, typically choose another product. Even though positive customer feedback can help businesses make significant financial advantages, it can also be taken into account when deciding how to design products and what services to give consumers [1].

This study is covered in around 36 articles in IEEE Xplore and 19 in Scopus. Multilayer Perceptron is derived from algorithms of Neural networks. Machine learning was used to perform forgery analysis on forgery observations [9]. Techniques for classifying products based on analysis and assessment of application models were developed. This initial Report was created utilizing machine learning approaches for forgery analysis [2]. Different algorithms were used to automatically detect forgeries, and the results showed higher accuracy. According to the study, articles have found that fake data reviews frequently contain longer sentences, more pauses, and duplicate phrases [5]. According to the use of various machine learning classification algorithms, it is possible to detect fake data reviews from genuine reviews with high accuracy using these language factors. The overall best cited article is of Forgery Analysis using Machine Learning Techniques [13].

When it comes to the algorithm and measuring of greater accuracy, even though many datasets are generated, it might be challenging to determine which is a legitimate dataset. The research gap of this article is to distinguish between genuine and fake data information because the majority of the currently employed standard feature extraction algorithms were created for quick analysis (Silva and da Silva 2020). Through the application of several machine learning approaches, this study seeks to increase the accuracy of forgery analysis. The aim of this article is to increase the accuracy values of forgery analysis with less complexity.

2. Materials and Methods

The research is done in the Saveetha School of Engineering's Machine Learning Lab at the Saveetha Institute of Medical and Technical Sciences in Chennai. This study states a comparison between the two classification algorithms [8]. For this work, there are 2 groups.

Novel MultiLayer Perceptron Algorithm is in Group 1 and Group 2 is composed of Gradient Boosting Algorithm. The sample size is given to each group 10 times. Alpha, beta, G-power, CI and threshold values for the study are 0.05, 0.2, 80%, and 95%, respectively.

The information was obtained from Kaggle, one of the free software programmes. The dataset is made up of several rows and columns, there are 7000 rows and 10 columns in this particular dataset. Dataset provides information about each customer like purchasing date, from which address and their personal details. The number of rows and columns defines the dataset and it is gathered from different platforms [6].

The parameters for both the hardware and software are in testing setup. Hard drive, 64-bit operating system of SSD chip and Intel Core i5 12th generation CPU, and 16GB of RAM are all features of the laptop. Now a Windows 11 collaboration application, it was created in Python. The accuracy value will be shown when the programme is finished. Procedure is that Wi-Fi is connected to the laptop through it. With aid of Google Collaborative tool is used to execute python code for present research work. After receiving an iteration of 10 accuracy values, save the file and keep the accuracy values in the SPSS application to get the final graphs and mean values.

2.1. Novel multilayer perceptron algorithm

Novel MultiLayer perceptron is a one of the Classification Algorithm, this algorithm is used for forgery analysis detection with an accuracy rate. The output is determined based on 3 functions which are within a range. By solving the error, final output will be defined.

Algorithm
Input: dataset K.
   Output: A testing dataset class
   Step 1: Dataset is Initialized.
   Step 2: Dataset is divided into categories of training and testing data.
   Step 3: Dataset will be given to the input of neurons.
   Step 4: The sum and weights are calculated on the basis of hidden layers.
   Step 5: By total of all weights and sum final output will be produced.

2.2. Gradient boosting algorithm

Gradient Boosting is a machine learning algorithm that states that after the classification of a dataset into decision trees, there may be a rise of errors in trees and each error can be done using gradient boosting parameters.

Algorithm

 Input: Dataset k

 Output: A testing dataset class

 Step 1: Input the dataset.

 Step 2: Separate the data for training and testing datasets.

 Step 3: After pre-processing the dataset, data is segregated in decision tree format.

 Step 4: For each tree follow the constraints of gradient boosting parameters.

 Step 5: Dataset can be validated finally.

2.3. Statistical analysis

The test was done by using the SPSS 29 version tool for calculating t-test values. The collaborative code's accuracy values are iterated ten times, with each iteration resulting in an assessment of the accuracy forecast [12]. A t-test was used to compare the significant values between two groups using independent samples. The forgery prediction is the dependent variable, whereas the components employed in the forgery analysis are independent variables.

3. Results

Two groups are compared in this research, Novel MultiLayer Perceptron and Gradient Boosting. Table 137.1 is about mean accuracy values and standard deviation of each group. The Table 137.2 is about the statistical data that showed that Novel MultiLayer Perceptron had the highest accuracy among the group.

 The mean accuracy of 84.2% and a standard deviation of 0.324. Gradient Boosting accuracy is on average 78.29%, with a standard deviation of 0.237.

The Novel MultiLayer Perceptron method has outperformed the Gradient Boosting algorithm. The results of the independent samples T-test for Novel MultiLayer Perceptron and Gradient Boosting are shown in Table 137.2. The average difference is 5.96 and 0.11 is the standard error of the difference. The results for these two algorithms are statistically significant differences with p values of 0.017. Figure 137.1 shows the bar graph comparison between two algorithms, Novel MultiLayer Perceptron over Gradient Boosting Algorithm.

4. Discussion

In this proposed work, the Novel MultiLayer Perceptron algorithm gives strong results with a low standard deviation and has a detection of forgery analysis accuracy of 84.2% in comparison to Gradient Boosting of 78.29%. The obtained significance value is 0.017 which is attained by using an independent sample.

 The results of earlier works of forgery analysis state that the Novel MultiLayer Perceptron approach has an accuracy rate of 77.8%. The Novel MultiLayer Perceptron in the current work, which is used to locate or identify forgeries in application evaluations, is said to have an accuracy rate of 84.2%. Yellapragada suggested the earlier research in 2021, and it shows that Novel MultiLayer Perceptron has an accuracy rate of 77.8% [11]. Another algorithm used or compared to ascertain forgery detection is the Gradient Boosting, which has an accuracy range of 78.1% and 78.29% for the current study [9]. Currently, a yelp dataset is used to forecast accuracy because it tends to offer it. In general, numerous algorithms have different accuracy ranges based on different datasets and their

Table 137.1. Group Statistics Results- Novel MultiLayer Perceptron has an mean accuracy (84.2%), whereas for Gradient Boosting has mean accuracy (78.29%)

	Algorithm	N	Mean	Std. Deviation	Std. Error Mean
Accuracy	NMLP	10	84.2530	.32486	.10273
	GB	10	78.2870	.13217	.04179

All the mean values are loaded into the SPSS software to obtain t-test, independent samples bar chart representation. X-axis represents Groups and Y-axis represents Mean accuracy. The accuracy mean is considered as 95% CI and +/- 2SD.

Source: Author.

application is growing to produce increasingly precise predictions [4]. Gradient Boosting has lower accuracy than Novel MultiLayer Perceptron when compared to other algorithms because it is a parameter that is utilized to quantify the forgery detection in both contemporary and traditional techniques to research on the particular document [14].

As the dataset's length reduces, the value of accuracy decreases, which is one of the aspects affecting the research. This study has limitations because it cannot produce training and testing accuracy datasets for smaller datasets. The future scope for the current work is to identify fraudulent and real reviews on applications using classification algorithms with great accuracy gains and little complexity.

5. Conclusion

In this study, forgery analysis detection utilizes the machine learning approaches, Novel MultiLayer Perceptron and Gradient Boosting are taken into consideration. The Novel MultiLayer Perceptron accuracy is 84.2%, and the Gradient Boosting output is 78.29%. Novel MultiLayer Perceptron is better when compared over Gradient Boosting.

138 Accurate usage analysis of a specific product based on Twitter user comments using random tree algorithm compared with AdaboostM1 algorithm

K. Venkata Sriram Subash[a] and T. Poovizhi

Department of Information Technology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The objective of the study is to assess the precision of AdaboostM1 and Novel Random Tree's analysis of product consumption based on user comments on Twitter. Novel Random Tree is used to achieve accuracy. The operations in this study that achieved the best accuracy for the analysis of a specific product's consumption based on Twitter user comments and opinion mining were carried out using the Novel Random Tree. There are 10 samples of Novel Random Tree and 180 samples of AdaboostM1 algorithms in 2 groups, iterated 10 times, executed with various training and testing splits for the prediction of product usage by division of positive and negative comments of the users. The Gpower value used is 85%. The significant value of $p=0.01$ indicates that the two groups are statistically significant. Hence the Product usage using Twitter comments has been implemented using Novel Random Tree with a significance value of 0.01 ($p<0.05$), Novel Random Tree (93.75%) outperforms AdaboostM1 (84.39%). Therefore, Novel Random Tree outperforms AdaboostM1 in terms of product consumption prediction accuracy.

Keywords: Novel random tree, AdaBoostM1, sentiment analysis, data mining, opinion mining, machine learning algorithms, social policies

1. Introduction

Sending important information from one location to another was the primary motivation for the development of the internet. Data transfer allows for the improvement of information and novel methods of dissemination to individuals. The product is advertised while going to the destination through social policies. Research Gate hosts 500 publications related to the study of product utilization, whereas IEEE has published 270 papers focused on product usage analysis. In 2020, Iglesias and Moreno. The marketing of a product requires careful consideration of the product. The majority of product producers will base their product launches on analysis, and Novel Random Tree will assist them in performing the analysis with the highest level of accuracy. The research study revealed the results of earlier studies that have shown less accuracy for the product analysis based on the user comments and this proposed algorithm has improved accuracy. Novel Random Tree gives us accurate results in analyzing the product and lets the manufacturers know about the user opinion based on the analysis. Data Mining helps in the identification of which product is more used by the users. The Novel Random Tree is used in this proposed system to improve accuracy in Product usage analysis.

2. Materials and Methods

The sample size was established by comparing the two remarks using the WEKA [7]. Software, while keeping a threshold of 0.05 and a G power of 80%. Two groups are picked to compare the process and the outcomes. For this investigation, 180 samples from each group were selected. Two algorithms, a support vector machine and a novel random tree are put into practise using technical analysis software.

The Intel Core i5 processor, 8GB of RAM, and 1TB of storage are features of the Dell Inspiron 153000

computer utilized for the anticipated study. Deep learning was tested on the Windows 10 OS. The system's sort had a 64-bit size. The Kaggle dataset [17] containing the Twitter entity sentiment analysis dataset was used in this study. This dataset includes several comments of different users. The size of the dataset is 50MB, Which consists of a total number of 180 comments. The data was split into Train and Test. The train dataset consists of 80 comments and the test consists of 70 comments. And the reference is taken from IEEE xplore [1]. The proposed work was created and completed using the Python OpenCV programme. Python programming was used to put the code into action. During code execution, the dataset is used to run an output step to ensure accuracy.

2.1. Novel random tree

The Novel Random Tree algorithm is a well-liked supervised learning technique in machine learning that may be used to solve classification and regression problems. It employs the ensemble learning approach and incorporates several classifiers to enhance model performance. It involves averaging a collection of SVMs that have each been trained on a different section of the dataset to improve prediction accuracy. Instead than relying on a single Support Vector Machine, the technique aggregates forecasts from each tree to forecast the final output using a majority vote procedure.

Algorithm

Step 1: Create a Dataset using GUI.

Step 2: Choose random samples from a data or training set.

Step 3: For each piece of training data, this algorithm will generate a decision tree.

Step 4: The decision tree will be averaged for voting.

Step 5: Finally, choose the prediction result with the most votes as the final prediction result.

2.2. AdaboostM1

AdaboostM1 is a statistical classification meta-algorithm. The results of the other learning algorithms, or "weak learners," are merged to create a weighted total that represents the boosted classifier's final results. Although AdaBoost can be used in many classes or bounded intervals on the real line, it is often shown for binary classification.

AdaBoost is adaptive in that it modifies future weak learners in favor of instances that prior classifiers incorrectly classified. It may be less prone to the overfitting issue than other learning algorithms in particular situations. It can be demonstrated that the final model converges to a strong learner even if the performance of each individual learner is just marginally better than random guessing. AdaBoost is frequently used to combine weak base learners (like decision stumps),

but it has been demonstrated that it can also combine strong base learners (like deep decision trees) well, leading to an even more precise model.

Algorithm

Step 1: Give each observation an equal weight. Initialize the dataset by giving each record the same weights.

Step 2: Sort arbitrary samples using stumps.

Step 3: Include a root node test case.

Step 4: Add target value leaf nodes.

Step 5: Backtrack to the root node.

2.3. Statistical analysis

This study used the SPSS (Version 26) software of IBM for statistical analysis [6] to compare the mean accuracies of the two algorithms. The independent Variables are User demographics, User behavior, and the dependent variables are Product, Product purchase intent. An independent sample test is performed.

3. Results

The proposed Novel Random Tree and AdaboostM1 models were run in Anaconda Navigator with a sample size of 10 at different times. The predicted accuracy and loss of Novel Random Tree are shown in Table 138.1. AdaboostM1 predicted accuracy and loss are shown in Table 138.2. These ten data samples are used by each algorithm, along with their loss values, to compute statistical values for comparison. According to the results, the mean accuracy of the Novel Random Tree was 93.75% and the AdaboostM1 was 84.39%. The mean accuracy values for Novel Random Tree and AdaboostM1 are shown in Table 138.3. The mean value of Novel Random Tree shows better accuracy than the AdaboostM1, with standard deviations of

Table 138.1. Accuracy and loss random tree

4. Discussion

Based on the type of comments submitted by users—positive or negative—the product analysis based on Twitter user comments will be carried out. Opinion mining will then be done for various users and their remarks utilizing

the Novel Random Tree (93.75%) in Table 138.5. There are numerous studies employing similar methods that analyze products based on user feedback. When compared to earlier research studies on product analysis, Novel Random Tree exhibits superior accuracy when utilized for the classification of comments, identifying product type, and product analysis for statistical implementation in SPSS.

Finding out can be challenging how the product is utilized and how it affects AdaboostM1's accuracy when using it to classify the comments and identify the dataset's features. However, in opinion mining, the Novel Random Tree can be utilized to locate the (Jena and Dehuri 2020) traits, keywords, and comments. It is also suitable for
Figure 138.1. Comparison of Novel Random Tree and AdaboostM1. Classifier in terms of mean accuracy and loss. The mean accuracy of the Novel Random Tree is better than the AdaboostM1. Classifier; Standard deviation of Novel Random Tree slightly better than AdaboostM1. X-Axis: Novel Random Tree vs AdaboostM1 Classifier and Y-Axis: Mean accuracy of detection with +/- 2 SD.

Source: Author.

both product type analysis and identification. Any dataset can be handled by the Novel Random Tree [5] with the best degree of accuracy. Using Novel Random Trees to examine data. The operation's temporal complexity has decreased as data volume has increased.

The classification and analysis of the product's usage based on user comments are both within the scope of the proposed work's limited constraints. If the relevant keywords and characteristics are missing from the dataset. The future scope of this activity includes classifying and analyzing the product as well as determining the necessary keywords and qualities.

5. Conclusion

The primary goal of this study is to investigate the functionality of a particular product. The product was tested using AdaboostM1 and Novel Random Tree models, which produced accuracy scores of 84.3950% and 93.7520%, respectively. Based on the analysis, it can be concluded that Novel Random Tree (93.7520%) outperforms AdaboostM1 (84.3950%) in terms of performance.

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: To enhance the accuracy and precision of movie reviews on Twitter by employing the Latent Dirichlet Allocation model and comparing its effectiveness with the Non-Negative Matrix Factorization technique. There are two groups of samples in the research study. The first group Latent Dirichlet Allocation includes 21 sample inputs and the group Non-Negative Matrix Factorization includes 21 samples, alpha value of 0.05 beta value of 0.2 and 80% G power is also being taken into consideration and the total sample size is 42. The accuracy of the Latent Dirichlet Allocation is 90% typically higher compared to 86% accuracy of the Non-Negative Matrix Factorization. The mean accuracy of the detection was found to be within +/- 2 standard Deviation, and a t-test using an independent sample showed that this result is statistically significant and got a significance value of p 0.009 (p<0.05). Performance of Latent Dirichlet Allocation is better than Non-Negative Matrix Factorization by comparing their results. The accuracy of Latent Dirichlet Allocation is higher than the comparison algorithm Non-Negative Matrix Factorization accuracy.

Keywords: Cinematic reviews, innovative topic modeling, latent dirichlet allocation, non-negative matrix factorization**,** movies, research, twitter

1. Introduction

Innovative Topic modeling is a method of identifying the underlying themes or topics present in a large collection of text data, such as movie reviews or tweets about movies. Latent Dirichlet Allocation is one algorithm that can be used for topic modeling, and it works by identifying the probability distribution of the words within each topic and the probability distribution of the topics within each document. Additionally, using topic modeling can help us to filter out irrelevant or extraneous information from the data, as it allows us to focus on the most relevant and important topics [23]. After preprocessing the data, Variety of techniques can be used to identify the main topics present within the text. Once the main topics present in our

dataset are identified, Information can be used to draw conclusions about popular movies and preferred film languages. Overall, the goal of our research will be to use Innovative topic modeling to understand trends and patterns in people's interests and preferences related to movies, as well as to identify the most popular movies and film languages. Latent Dirichlet Allocation as a prediction model to analyze a large dataset of tweets related to movies in order to understand trends and patterns in people's interests and preferences. LDA is a probabilistic model that is commonly used in topic modeling, which is a method of unsupervised machine learning that involves identifying the main themes or topics present in a large corpus of text data. The utility of Innovative topic modeling is restricted to analyzing textual data alone, and its effectiveness is influenced

by subjective decisions made during the preprocessing and modeling stages, such as the selection of the number of topics and the algorithm used. This makes it a useful tool for analyzing social media data, such as tweets, in order to understand trends and patterns in people's interests and preferences.

2. Materials and Methods

The Saveetha School of Engineering's Artificial Intelligence Laboratory served as the site of the research for this project (SIMATS). The effectiveness of Latent Dirichlet Allocation and Non-Negative Matrix construction are contrasted in the study. Two groups are mentioned in the study group 1 refers to Latent Dirichlet Allocation and group 2 refers to Non-Negative Matrix Factorization. Allocation using Latent Dirichlet works better. G-power is the name of the software package used to obtain power analysis. The sample size computation with the G-power tool employed 42 samples with an 80% g-power value.

The dataset needed for this research must contain details on topic modeling that are important for determining correctness. For straightforward access to the processor, the framework needs a minimum of 4GB of RAM. In terms of the processor, Ryzen 4 or an Intel i5 6th generation are suggested. To save the necessary pictures of the dataset that are downloaded from kaggle, as well as to store the code and install plugins or any other software, at least 50GB of hard disc space is needed [9]. A graphics card with at least 2GB of memory is advised to lessen the load on the CPU and aid in the collection of information from recent datasets. The subject modeling is created using the online development environment Kaggle [11].

2.1. *Latent dirichlet allocation*

Latent Dirichlet Allocation (LDA) is a probabilistic model that is commonly used for Innovative topic modeling in natural language processing (NLP) tasks. It is based on the idea that each document in a collection can be represented as a mixture of a small number of Latenttopics, and each topic is a distribution over a vocabulary of words. LDA assumes that the words in a document are generated by sampling from the topic distribution, and the topic distribution for each document is generated by sampling from a document-level topic distribution. In other words, LDA represents documents as a combination of topics, and topics as a combination of words. This allows LDA to identify the main themes or topics present in a collection of documents, and to identify the words that mostly belong to each topic [27]. LDA is often used to automatically discover the underlying structure of a large corpus of text,

and it has many applications in information retrieval, document classification, and text summarization.

Algorithm
Step 1: In the Latent Dirichlet Allocation (LDA) model, M is the total number of documents in the corpus, N is the number of words in a document, w is a word in a document, and z is the latent. Topic assigned to a word. Theta (θ) is the topic distribution for a document, and alpha (α) and beta (β) are the model's parameters.

Step 2: Each document is represented as a distribution over topics, and each topic is represented as a distribution over words. The model assumes that each document is a mixture of a fixed number of topics, and that each word in the document is drawn from one of those topics. The model estimates the parameters of the model (alpha and beta) using the words in the documents and their corresponding topic assignments.

Step 3: The goal of the LDA model is to uncover the hidden topic structure in a collection of documents. It does this by finding the set of topics that are most probable given the words in the documents and their corresponding topic. The model can then be used to classify the documents.

2.2. *Non-negative matrix factorization*

Non-Negative Matrix Factorization (NMF) is a method for decomposing a Matrix into the product of two matrices with Non-Negative elements. It is often used for dimensionality reduction and feature extraction, as well as for data compression. In NMF, the goal is to find two matrices, W and H, such that V ≈ WH, where V is the original data Matrix, W is an n x r Matrix, and H is an r x m Matrix. The values in the matrices W and H are constrained to be Non-Negative, which means that they cannot be Negative or zero [7]. The Matrix W is called the basis Matrix and represents the Latent (hidden) features of the data, while the Matrix H is called the coefficient Matrix and represents the weights or contributions of these features to the data vectors. The process of finding the matrices W and H that approximate V is often called "unfolding" the data Matrix. NMF has a number of applications in data analysis, including document clustering, image analysis, and gene expression analysis. It can also be used for data compression, since the matrices W and H are typically smaller than the original Matrix V.

Algorithm
Step 1: W and H are the two factorizes matrices of the Non-Negative Matrix Factorization

Step 2: One way to think about NMF is as a type of dimensionality reduction method, where the goal is to represent the original data Matrix A in a

lower-dimensional space using the matrices W and H. This is because the dimensions of W and H are typically significantly smaller than the dimensions of A, and each column in W and H can be interpreted as a "hidden feature" or "Latent Factor" that contributes to the data in A.

Step 3: Intuitively, NMF assumes that the data in A can be represented as a combination of a small number of underlying factors or patterns, and these factors are represented by the columns in W. The weights associated with these factors for each data point are represented by the corresponding column in H. This allows NMF to represent the data in A in a more concise and interpretable way, while still preserving as much of the original structure and information as possible.

2.3. *Statistical analysis*

The analysis entails processing and evaluating the accuracy results from testing the suggested concept utilizing both algorithms using statistical analysis tools such as SPSS (Statistics Tool for Social Sciences). The machine used in the study has an 8GB RAM, 256 HDD, and Windows 10 CPU [22]. The research work is analyzed using an independent sample t-test, which is utilized to evaluate cinematic review tweets. The accuracy is the dependent variable in the research study, which also includes the independent variables of number of words, relevant topics, length of sentences and language [8,22].

3. Result

In summary, the superiority of LDA over NMF in topic modeling for Twitter data highlights the importance of carefully selecting an appropriate model that is best suited for the specific characteristics of the data being analyzed. On this particular sample and task, Table 139.1 shows that the Latent Dirichlet Allocation technique outperformed the Non-Negative Matrix Factorization algorithm. The mean accuracy in Latent Dirichlet Allocation is 82. Latent Dirichlet Allocation and Non-Negative Matrix Factorization have standard deviations of 4. For Groups 1 and 2, the standard error means are, respectively. The choice of statistical test will rely on the details of our data, including the distribution

of the accuracy scores and the sample size, as shown in Table 139.3. Bar chart comparison of the performance of two different algorithms (Latent Dirichlet Allocation and Non-Negative Matrix Factorization) in terms of accuracy as depicted in Figure 139.1. The gain and loss value of the accuracy can be calculated and plotted on the y-axis of the graph. Based on the information provided, it appears that the Latent Dirichlet Allocation

Table 139.1. The sample size of N = 42, 21 data has been added in the single sample size for each group. 21 values of Accuracy rate have been taken to two different algorithms. The highest Accuracy is 90 which is available in Latent Dirichlet Allocation. Latent Dirichlet Allocation has more accuracy than Non-Negative Matrix Factorization

algorithm had a higher accuracy than the Non-Negative Matrix Factorization algorithm, with a significance of 0. 05 level and also mentioned that the mean accuracy of the data was plotted with a range of +/-2 standard Deviation in Figure 139.1.

4. Discussion

In analyzing Twitter data using topic modeling, Latent Dirichlet Allocation and Recurrent Non-Negative Matrix Factorization are two popular algorithms used. This can be attributed to the probabilistic nature of LDA that is better suited for the informal and diverse language of Twitter data compared to RNMF. In conclusion, LDA has proven to be an effective tool for topic modeling in Twitter data with high accuracy rates. In their research, Latent Dirichlet Allocation algorithm was used to obtain a topic modeling accuracy of 76% in Table 139.2–139.3. Similarly, Used the LDA algorithm and achieved an accuracy of 78%

in identifying topics from large data [14]. Another study applied the Non-Negative Matrix Factorization algorithm and reported an accuracy of 74% for relevant topic detection. The research author also used the Non-Negative Matrix Factorization algorithm in Innovative topic modeling and obtained an accuracy of 75%. It is important to note that the specific results and findings of our study will depend on the specific dataset and analysis procedures used. To better understand the results, it may be helpful to provide more details about the dataset, the analysis procedures, and the specific findings that were obtained. The report suggests that modifications can be made to the topic modeling algorithm to improve its performance.

5. Conclusion

Latent Dirichlet Allocation outperforms Non-Negative Matrix Factorization in the study, with an accuracy of 90% for Latent Dirichlet Allocation and an accuracy of 86% for Non-Negative Matrix Factorization. In terms of accuracy, Latent Dirichlet Allocation outperforms Non-Negative Matrix Factorization in the unique topic modeling of twitter data in film reviews.

140 Improving the accuracy of cinema review topic modeling on Twitter with parallel latent Dirichlet allocation and latent Dirichlet allocation

Leela Krishna K.[a] and Surendran R.

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The primary objective of research is to compare the Latent Dirichlet Allocation model and Parallel Latent Dirichlet Allocation to improve the accuracy and precision of movie reviews on Twitter. The first group Latent Dirichlet Allocation includes 21 sample inputs and the group Parallel Latent Dirichlet Allocation includes 21 samples, alpha value of 0.05 beta value of 0.2 and 80% G power is also being taken into consideration and total sample size N is 42. The accuracy of the Latent Dirichlet Allocation is 90% typically higher compared to the 89% accuracy of the Parallel Latent Dirichlet Allocation. The mean accuracy of the detection was found to be within +/- 2 standard Deviation, and a t-test using an independent sample showed that this result is statistically significant and got a significance value of P is 0.023(p<0.05). Performance of Latent Dirichlet Allocation is better than Parallel Latent Dirichlet Allocation by comparing their results. The accuracy of Latent Dirichlet Allocation is higher than the comparison algorithm Parallel Latent Dirichlet Allocation accuracy.

Keywords: Cinematic reviews, innovative topic modeling, latent dirichlet allocation, parallel dirichlet allocation, research, twitter

1. Introduction

Innovative Topic modeling is a machine learning technique that is used to discover the underlying topics in a collection of documents. It is a type of text analysis method that analyzes groups of words, or "bags," together in order to capture the meaning of words in the context in which they are used in natural language. A variety of strategies to determine the primary subjects included in the text after preprocessing the data. Our research will employ Innovative topic modeling to investigate trends and patterns in people's interests and preferences in movies, as well as to pinpoint the most well-liked films and film languages and can learn more about the movie business and contribute to future decision-making in this field by conducting this research [15]. In order to study trends and patterns in people's interests and preferences, researchers used Latent Dirichlet Allocation as a prediction model to examine a large dataset of tweets about movies. Identifying the key themes or topics contained in a sizable corpus of text data is the goal of Innovative topic modeling, an unsupervised machine learning technique, which frequently employs the probabilistic model of LDA. Each document in the corpus is thought to be a combination of a few Latent topics, and each word in the document is assumed to be derived from one of those subjects. The most likely Latent topics present in each document and the most likely words that relate to those subjects are subsequently determined using Bayesian inference. Innovative Topic modeling is limited to analyzing text data, Topic modeling is sensitive to the subjective choices made during preprocessing and modeling, such as the number of topics selected and the choice of algorithm. LDA's ability to handle enormous volumes of text data and recognise the primary themes or topics contained within that data is one of its significant features.

2. Materials and Methods

This research project was conducted at the Saveetha School of Engineering's Artificial Intelligence Laboratory.

The goal of the study was to compare the effectiveness of two groups, Group 1 refers to Latent Dirichlet Allocation and Group 2 refers to Parallel Latent Dirichlet Allocation. The results of the study indicated that Latent Dirichlet Allocation performed better than Parallel Latent Dirichlet Allocation. G-power software was used to conduct a power analysis and determine the sample size for the study. The sample size was calculated to be 42 samples, with a g-power value of 80%. This research requires a dataset with relevant information about topic modeling in order to accurately evaluate the performance of the algorithms being studied. The computer used for the analysis should have at least 4GB of RAM for optimal performance, and a processor such as a Ryzen 4 or an Intel i5 6th generation is recommended [9]. To store the dataset and other necessary files, the computer should have at least 50GB of hard drive space available. A graphics card with at least 2GB of memory is recommended to help with the processing of large datasets. The Innovative topic modeling was implemented using the online development environment Kaggle.

2.1. *Latent dirichlet allocation*

Latent Dirichlet Allocation (LDA) is a statistical model that is widely used for topic modeling in natural language processing tasks. It assumes that each document in a collection can be represented as a combination of a small number of Latent topics, and that each topic is a distribution over a set of words [1]. LDA allows documents to be represented as a mixture of topics, and topics to be represented as a mixture of words. This enables LDA to identify the main themes or topics present in a collection of documents, as well as the words that are most likely to belong to each topic. LDA is often used to automatically discover the underlying structure of a large corpora of text and has many applications in information retrieval, document classification, and text summarization.

Algorithm
Step 1: In the Latent Dirichlet Allocation (LDA) model, each document in a corpus is represented as a distribution over a set of topics, and each topic is represented as a distribution over a set of words.

Step 2: The model assumes that each document is a mixture of a fixed number of topics, and that each word in the document is drawn from one of those topics. The model estimates the parameters of the model (alpha and beta) using the words in the documents and their corresponding topic assignments.

Step 3: LDA discovers the hidden topic structure in a collection of documents by finding the set of topics that are most probable given the words in the documents and their corresponding topic assignments. The model can then be used to classify new documents or to find similar documents in the corpus.

2.2. *Parallel latent dirichlet allocation*

Parallel Latent Dirichlet Allocation (PLDA) is a probabilistic graphical model used in natural language processing (NLP) to identify the underlying topics in a set of data observations. It is considered a type of topic model, where documents are represented as mixtures of topics and these topics are composed of words [19]. In PLDA, a dictionary of words with unique identifiers is created and a written text containing the entire document data is provided. The goal of PLDA is to extract the input data and identify the output topics. PLDA can also be used in a backward direction.

Algorithm
Step 1: Select the area or domain where the algorithm will be applied.

Step 2: Determine the number of words in the documents of the selected area.

Step 3: Choose a topic from a set of mixed documents.

Step 4: Select a multinomial document from the chosen topic based on its distribution.

2.3. *Statistical analysis*

The data will be analyzed using statistical analysis tools such as SPSS. The machine used in the study has 8GB of RAM, a 256 HDD, and a Windows 10 CPU [8]. The accuracy of the suggested concept will be evaluated by processing and analyzing the results of testing it using both algorithms. The research work is analyzed using an independent sample t-test, in this research study, the accuracy is being measured and analyzed. The independent variables being considered are independent variables of number of words, relevant topics, length of sentences and language [7].

3. Result

In Table 140.1, on this particular sample and task, the Latent Dirichlet Allocation algorithm outperformed the Parallel Latent Dirichlet Allocation algorithm. In Table 140.2 This study compared the accuracy of two algorithms, Latent Dirichlet Allocation and Parallel Latent Dirichlet Allocation, using independent samples. The mean accuracy for the Latent Dirichlet Allocation group was 82. 455, while the mean accuracy for the Parallel Latent Dirichlet Allocation group was 79.767. The standard deviation for the Latent Dirichlet Allocation group was 4. 2444 and the standard deviation for the Parallel Latent Dirichlet Allocation group was 3.3880. The standard error mean for the Latent Dirichlet Allocation group was 0. 9262 and the standard error mean for the Parallel Latent Dirichlet Allocation group was 0.7393. This visual representation allows for a quick and easy comparison of the accuracy of the two

Table 140.1. For this study, a sample size of N=42 was used, with 21 data points for each group. The accuracy rates of the two algorithms were analyzed using 21 values. The highest accuracy was 90, which was found in the Latent Dirichlet Allocation group. The Latent Dirichlet Allocation algorithm had a higher accuracy rate than the Parallel Latent Dirichlet Allocation algorithm

algorithms. The mean accuracy of the data was plotted with a range of +/- 1 standard Deviation.

4. Discussion

Parallel Latent Dirichlet Allocation and Latent Dirichlet Allocation are two models used for topic modeling in Twitter data. Overall, LDA has been found to be a more effective tool for accurate topic modeling in Twitter data compared to PLDA in Figure 140.1. In the study, Appears
Figure 140.1. A bar graph can be used to visually compare the accuracy of Latent Dirichlet Allocation and Parallel Latent Dirichlet Allocation. The difference in accuracy can be plotted on the y-axis, while the x-axis can represent the two algorithms being compared. The bar graph shows that the Latent Dirichlet Allocation algorithm had a higher accuracy than the Parallel Latent Dirichlet Allocation algorithm, but the difference was not statistically significant at the 0.05 level, with a p-value of 0.029 (p<0.05). The mean accuracy of the data was plotted with a range of +/- 2 SD.

Source: Author.

Table 140.2. This study compared the accuracy of two algorithms, Latent Dirichlet Allocation and Parallel Latent Dirichlet Allocation, using independent samples. The mean accuracy for the Latent Dirichlet Allocation group was 82.457, while the mean accuracy for the Parallel Latent Dirichlet Allocation group was 79.767. The standard deviation for the Latent Dirichlet Allocation group was 4.2444 and the standard deviation for the Parallel Latent Dirichlet Allocation group was 3.388. The standard error mean for the Latent Dirichlet Allocation group was 0.9262 and the standard error mean for the Parallel Latent Dirichlet Allocation group was 0.7393

	Algorithm	N	Mean	Std. Deviation	Std. Error Mean
Accuracy	Latent Dirichlet Allocation	21	82.457	4.2444	.9262
Accuracy	Parallel Latent Dirichlet Allocation	21	79.767	3.3880	.7393

that used LDA to analyze Twitter data related to movie reviews. In their research, Latent Dirichlet Allocation algorithm was utilized to obtain a topic modeling accuracy of 76% [14]. Similarly, Used the LDA algorithm and achieved an accuracy of 78% in identifying topics from large data. In another study applied the Parallel Latent Dirichlet Allocation algorithm and reported an accuracy of 74% for relevant topic detection. Likewise, the research author also used the Parallel Latent Dirichlet Allocation algorithm in topic modeling and obtained an accuracy of 75%. These algorithms are utilized in Innovative topic modeling to evaluate the model's performance and identify potential areas for improvement or optimization in Table 140.3. According to the report changes can be made in the algorithm. Some of them are topics generated by topic modeling algorithms that may not always be easily interpretable by humans, topic modeling is sensitive to the subjective choices made during preprocessing and modeling.

5. Conclusion

According to the study, Latent Dirichlet Allocation (LDA) surpasses Parallel Latent Dirichlet Allocation (PLDA), with an accuracy of 90% for Latent Dirichlet Allocation versus 89% for Parallel Latent Dirichlet Allocation. This suggests that, in the case of creative topic modeling of Twitter data in film reviews, LDA outperforms PLDA in terms of accuracy.

141 Modeling and analysis of the return loss and gain performances of innovative meander-loaded triangular antenna and OCSRR-embedded triangular antenna for low-frequency applications

Tirupati Lakshmidhar[a] and Anitha G.

Institute of Electronics and Communication Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: To assess the disparities in loss of return and gain performance between the newly designed meander-loaded triangle antenna and the OCSRR embedded triangle antenna at the input frequency of 1.8 GHz, focusing on their 50 Ω impedance characteristics for applications in the L band frequency range. Materials and Methods: The effectiveness of a Meander-loaded triangular antenna and an OCSRR-embedded triangular antenna was assessed concerning their return loss with a characteristic impedance of 50 Ω. For 34 measurements, analytical number of participants contains 17 occurrences of each antenna. Result: In terms of return loss, the novel meander-loaded triangle antenna outdoes the OCSRR Embedded triangle antenna substantially. The loss of return for Meander-loaded triangular antenna was -31.2284, whereas the OCSRR Embedded triangular had a loss of return of -24.1400. The size of both antennas was 85mm by 80mm. The attained significant value in Gain p is 0.000 (p<0.05) and return loss p data is .042 (p<.05). Conclusion: The Meander loaded triangle demonstrated superior performance compared to the OCSRR Embedded triangular antenna in the means of Loss of Return, measuring at an impressive -31.2284. These results indicate that the Meander loaded triangular is better suited for applications in the L-band frequency range.

Keywords: Novel meander loaded triangle antenna, OCSRR embedded triangle antenna, RF performances, communication technology

1. Introduction

In this research, we explore two novel antennas designed for L Band applications: the Meander Loaded Triangle Antenna and the OCSRR Embedded Triangular Antenna. By thoroughly simulating as well as comparing the amount of signal reflection and gain performances, we aim to gain valuable insights into their potential practical applications. This study contributes to the advancement of antenna technology and its suitability for various wireless communication systems. This document [1] presents a concise account of the compact, serpentine-formed slot-occupied rectangular aerial for employment in C and X band applications, utilizing defected ground structure. By introducing a unique slot with the sierpinski fractal, size reduction is investigated. Ant 1 operates at 15.9 GHz (S11: -33.47 dB), while miniaturized Ant 2 operates at dual-band frequencies of 6.85 as well as 10.5GHz along S11 values of -24.26 as well as -32.47dB, achieving 56.9% and 33.96% size reductions. Antenna dimensions are 16×16×0.8 mm³, surfaced on a RT Roger Duroid substrate. Parametric reviews and simulated radiation components are included. In this [2] a novel triangular Oxalis leaf-shaped snowflake fractal patch antenna is designed for wireless communication, showcasing versatile behavior in S, C, and X bands. Its innovative structure includes a meander-snowflake curve on the

ground, enabling multiband operation. With distinct return loss values at various frequencies, the antenna outperforms existing ones, validated through extensive study. This research [3] introduces an efficient dual-band meandered loop antenna designed for RF energy harvesting applications. Operating at frequency modulation (95 MHz) and Global system for mobile communication Band (925 MHz), modified folded dipole antenna achieves proper gain. Antenna's unique design results in an electrically small form factor (35 cm × 35 cm at FM band), eliminating the use of an Circuit for Achieving Impedance Matching. With omnidirectional patterns, with peak gains reaching 1.1 dBi for FM and 3.2 dBi for GSM, this device emerges as a promising contender for RF energy harvesting and wireless power transfer applications. This paper [4] states that a unique design of CP radiation is proposed using a meandered quarter-mode circle. Two antennas are presented with different slot configurations to manage loss of return and phase shift changes. Antenna-1 (A1) exhibits a 10dB bandwidth of 1.24GHz (4.52–5.76GHz) and a 3dB AR bandwidth of 200MHz (4810–5010MHz), with a gain of 5dBic. Antenna-2 (A2) shows a 10dB bandwidth of 1.21 GHz (4.5–5.71 GHz) and a 3 dB AR bandwidth of 120MHz (4830–4950MHz) with the same gain. Fabricated and simulated analysis is provided.

2. Related Study

There have been a number of publications written recently on this subject. 44 Science Direct journals and 2080 in the Google Scholar papers are published in the preceding five years of duration. In this scholarly article [5], an innovative ultra-wideband (UWB) monopole antenna featuring a pentagonal configuration is introduced within this study. The suggested design integrates a patch with a pentagonal shape and employs the meander fractal methodology with dual repetitions along all perimeters of the patch. Through the utilization of the meander fractal approach, the bandwidth is expanded, leading to an enhanced effective path length of current and a diminished frequency of 2.63 GHz within the UWB spectrum. The formulated antenna attains an S11 parameter below -9.5 dB across the 2.63 GHz to 12.0 GHz range, rendering it well-suited for diverse UWB applications. The antenna exhibits an omnidirectional radiation pattern as confirmed from the measured performance. It is implemented on a single-layered FR4 substrate, measuring 20×33×1.6mm³. The antenna characteristics, as deduced from both simulations and actual measurements, exhibit strong concurrence, affirming its effectiveness and suitability for implementation in ultrawideband (UWB) communication setups. This paper [6] introduces UWB structure,

starting along a triangular microstrip antenna adapted for the 3.1–10.6 GHz range. Structural enhancements, including a meandered line edge-cut, partial ground, and ground slots, led to a final UWB monopole design with an impressive 8.4 GHz bandwidth (125.74%) from 2.48 to 10.88GHz and a gain peak of 7.23dB. Comprehensive comparisons were made for each design stage, and fabricated results matched the simulations well.

One of the main downsides of the OCSRR Embedded triangular antenna is its low Return Loss performance. Many efforts have been made to improve these performance metrics, including repositioning and orienting the antenna design within the patch. This study compares the Return Loss performance of a Meander loaded triangle antenna with an OCSRR Embedded triangle antenna at 1.8 GHz. The goal of this study is to discover techniques for improving the Return Loss performance of these types of antennas.

3. Methodology

The findings of two different preparation procedures are presented in this study. In Group 1, a Novel Meander Loaded Triangle Antenna was designed and simulated using HFSS software. The chart depicts the measurements of the key parts, including the foundation, substrate, patch, transmission line, and feed. This program was used to model and develop the Novel Meander Loaded Triangle Antenna. The training for Group 2 was indistinguishable from that of Group 1. Group 2 utilized HFSS software to design and simulate a OCSRR Embedded Triangle Antenna. This software was employed to complete the simulation and construction of the OCSRR Embedded Triangle Antenna, and the measurements of the various parts, including the ground plane, substrate, patch, feedline, and feed, are provided in Table 141.1.

HFSS is finite element of EM structural solution used to design antennas, and radio frequency electrical components including filters, transmission lines, and packaging. It is implemented in the form of a comprehensive Ansys standard. HFSS was utilized in this work to measure the RF performance of the unique triangular Meander Loaded Antenna and a OCSRR Embedded Triangle Antenna by keeping the frequency at 1.8 GHz and recording the results. SPSS, a statistical tool is frequently used to compute standard deviations, mean values, and identify statistically substantial variations in data from simulations.

Position a base material over the reference plane and position a patch over the base material, Table 141.1 displays the information regarding measurements that was used to make the triangular pattern above the patch. With FR4 epoxy fixed as the substrate

material, a feed was attached to the patch. The design was looked at and the results were verified in Figure 141.1. For the Group 2 samples, the identical process was used, but modifications to the patch's size and design were made in accordance with the values shown in Table 141.1. These procedures aided the modeling and evaluating process, allowing the attainment of the required outcomes for both the unique triangular Meander Loaded Antenna (Group 1) and the OCSRR Embedded Triangle Antenna (Group 2), which were both new antenna designs.

4. Statistical Analysis

Both of SPSS and HFSS were crucial components of this investigation, along HFSS being utilized for model as well as validation and SPSS being utilized for statistical information analysis. Frequency and dielectric depth were the only variables that were independent

Table 141.1. The dimensions of the innovative meander-incorporated triangular antenna and the OCSSR-embedded triangular antenna are as follows. The patch width (WP) of the triangular slot is 50.55 millimeters, and the triangular slot itself is also 50.55 millimeters wide

taken into account in the examination, whereas other variables changed. At the opposite hand, the dimension, placement, and impedance matching of the patch were among the variables that depended factors being examined in Figure 141.2. To comprehend their effects and behaviors inside the antenna system, these factors underwent rigorous examination.

5. Results

The novel Meander loaded triangle antenna and the OCSRR Embedded triangle antenna were built and tested effectively at 1.8 GHz with a characteristic impedance of 50 Ω. The testing of the input employed the defined parameters, and the findings were derived from defining specific boundaries and excitations within the model. After generating the graph, it was saved in the form of an Excel spreadsheet. Subsequently, the data set was transferred to SPSS for further statistical research.

At 1.8 GHz, Table 141.2 compare the performances of RF of the unique Meander loaded triangle antenna and OCSRR with the triangle slot antenna. When these statistics are compared, the Meander loaded triangular antenna has got a better return loss (-31.2284) than the OCSRR Embedded triangle antenna. The distinctive meander-loaded triangular antenna has a lower return loss of -31.2284 than the oscillating complementary split ring resonator (OCSRR) with the triangular slot antenna. As a result, the distinctive meander-loaded triangular antenna is most suitable for applications in the L-band.

Picture1 and Picture2 show the overhead and facade perspectives of unique Meander loaded triangular antenna as well as the OCSRR Embedded triangular antenna, respectively. Picture3 depicts the loss of return for Meander loaded triangle as well as the OCSRR Embedded triangle. Figure 141.4, a graphical representation of the two antennas' return loss efficiency shows that the meander-loaded triangular antenna outperforms the OCSRR embedded triangular antenna in both aspects.

6. Discussion

Loss of Return efficiency for the Meander loaded triangular antenna as well as the OCSRR Embedded triangular antenna underwent construction and testing. Meander loaded triangle antenna outperforms the OCSRR Embedded triangular antenna regarding Return Loss performance. The data was then entered into an excel spreadsheet and validated using SPSS software.

In this investigation, we offer the simulation and contrast of the meander-loaded triangular antenna and the OCSRR embedded triangular antenna on a 50 ohm distinctive impedance at 1.8 gigahertz. This manuscript [7] portrays an exploration of a triangular-shaped meander line antenna operating at 2.45 GHz. The main focus lies on its design, simulation, and efficiency assessment. The investigation includes extensive parameter studies that consider factors such as coils, wire width, ground breadth, length, and wire separation. The objective is to achieve the optimal gain for the meandering line antenna. The simulation

Table 141.2. Antenna performance of Novel Meander loaded triangular antenna and OCSRR triangle patch antenna

Antenna	Return loss (dB)	VSWR	Gain (dB)	Bandwidth (%)
Innovative Meander loaded triangular antenna	−31.2284	1.0565	2.42	53.0 MHz
CSRR Embedded triangle antenna	−24.1400	1.0799	2.4	49.2 MHz

Source: Author.
Figure 141.3. Comparing the Meander loaded triangle antenna (−31.2284 dB) and OCSRR Embedded triangle antenna (−24.1400 dB) by its performance in loss of return.

Source: Author.
Figure 141.4. OCSRR Embedded triangle antenna performance compared to unique Meander loaded triangle antenna in a bar chart for Return Loss and Gain. The Meander loaded triangle antenna has a high return loss performance (blue bar), a low VSWR performance (red bar), and a high gain performance (green bar). The performance of a Meander loaded triangle antenna appears to be superior to that of a OCSRR Embedded triangle antenna.

Source: Author.

used HFSS software to analyze the antenna's performance on a 1.6-millimeter-thick FR4 substrate with a dielectric permitivity of 4.6. Several metrics, such as Total efficiency, Radiation efficiency, S11, and VSWR (-4.499dB, -4.498dB, 2.45GHz, 1.0241), are computed. Proposed antenna demonstrates potential applicability in WLAN systems in Figure 141.3.

The two most essential factors influencing an antenna's gain performance are patch size and frequency. The effective magnitude of a antenna is intricately tied to its enhancement at a designated frequency, whilst the effective measurement is associated with the square root of the antenna's enhancement at said frequency and radiation impedance. Owing to reciprocity, the amplification of each antenna while in the process of receiving remains indistinguishable from its amplification during transmission. It may be possible to increase the gain of an antenna by incorporating alternate substrates and metamaterials on the patch, or by partially cutting slots in the substrate and using multi-layer dielectric substrates.

7. Conclusion

The objective of this investigation was to improve the return loss efficiency of the innovative Meander loaded triangle antenna and the OCSRR Embedded triangle antenna at 1.8 GHz. The Meander loaded triangle antenna outperformed the OCSRR Embedded triangle antenna concerning performance (Return Loss:

-31.2284). These findings imply that the Meander loaded triangular antenna is better suited for L-band applications.

142 Braille character recognition for blind people using MobileNet compared with LSTM model

T. Sudeer Kumar[a] and S. Mahaboob Basha

Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institution of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The purpose of this study is to improve the rate of braille character recognition (BCR) for the blind using the novel MobileNet algorithm in comparison to the long short term memory (LSTM) algorithm. The research dataset used in this study was sourced from the Kaggle database system. The prediction of braille character to text translation with an enhanced accuracy rate was based on a sample size of twenty (ten from Group 1 and ten from Group 2), and the calculation was carried out using a G-power of 0.8, with alpha and beta values of 0.05 and 0.2, and a confidence interval of 95%. MobileNet and long short term memory, both with the same amount of data samples (N=10), are used to perform the prediction of the input image, identify braille characters, with MobileNet achieving a better accuracy rate. The accuracy rate of the proposed MobileNet is 98.05 percent, which is significantly higher than the success rate of the long short term memory classifier, which was 94.33 percent. The level of significance that was assessed to be attained by the research was p = 0.035. The proposed MobileNet model accomplishes a higher level of accuracy in terms of the performance evaluation of braille character recognition than the long short term memory model does.

Keywords: Braille character recognition, novel MobileNet, long short term memory, accuracy, translation, braille dots, blind people

1. Introduction

Braille letters are created for the blind and consist of six embossed dots arranged in a predefined pattern [2]. The purpose of this project is to develop a system for recognizing braille characters and translating them into alphanumeric text. Then, a novel MobileNet approach is employed to recognize braille characters, and the results are compared to long short term memory The projected system is split into 3 phases: aggregation input images, extracting options for coaching the deep learning model, and evaluating performance On the public double-sided Braille picture collection and gathered handwritten Braille document images, the experimental findings demonstrate that the suggested framework is more universal, resilient, and efficient for recognising Braille letters. The Braille system can be found in a wide variety of applications, including account statements, train tickets, directions, and musical transcription [16]. Several methods have been proposed in the literature to identify braille characters

over recent years [4, 8, 17] proposal for bidirectional Hindi and Odia Braille text transcription using unicode. In addition to outlining and contrasting the benefits and drawbacks of the current database, the study in offers a brand-new handwritten character database. In order to recogzise the Braille used in Japan, Zhang and Yoshino employed photos taken with a mobile phone and image processing methods. A Support-Vector Machine was utilized by Li and Yan to identify Braille letters in a picture. In a previous method, a multi-layer perceptron neural to translate Braille dots into Braille letters, they also produced a Braille grid based on the Braille organisation principles.

2. Materials and Methods

The research was carried out in the Computer Science and Engineering Department's Software Laboratory at Saveetha University. In this particular research study, the dataset was obtained from the Kaggle repository. The database is structured so that 75% of it is

dedicated to training, and 25% is for testing. There are two sets taken, and each set has ten data samples; the total number of samples taken into consideration is twenty. Group 1 was a long short term memory (LSTM) method and Group 2 was a novel MobileNet algorithm. Matlab software is used to generate the output for the braille character recognition model. The sample size was determined by using previous research from [5] at clinicalc.com. The threshold for the calculation was set at 0.05, the G power was set at 80%, and the confidence interval was set at 95%.

2.1. Long short term memory (LSTM)

Recurrent neural networks (RNNs) called Long Short-Term Memory (LSTM) systems are capable of understanding order dependency in circumstances involving sequence prediction. RNN is a feed-forward neural network that stands out for having internal memory. The output from one stage is used as an input for the next in this network; after being produced, the output is repeated and sent back to the RNN. The network aids in deciding the order of the photos by analysing data about the input and output it got from the previous input during the decision-making step. LSTM networks may be used in a variety of contexts, including activity recognition, language learning, handwriting recognition, human action recognition, image explanation, rhythm research, time series modelling, voice identification, and video specification. If the input unit has high activity, the data is stored in the memory cell. Moreover, if the output unit is highly activated, it will transmit the information to the following neuron. Otherwise, input data with a high weight is stored in the memory cell. LSTM networks may recall or forget values because their switching gates are constructed with a sigmoid function and a point.

    Step 6: For each tgt()
    Step 7: = Difference among _ tgt * i
    Step 8: Set Error learning to (dec_space * 0.2)

    Step 9: Initialize all weights in network randomly. { for hidden layer. for Output layer}
    Step 10: Set learning-condition to false
    Step 12: Set iteration to zero
    Step 13: For every pixel $Gixy$ {$0x$ image width, $0y$ image length}
    Step 14: If any pixel in line $y = 0$ then
    Step 15: For every pixel $Gix,y+1$
    Step 16: If all pixels in line $y+1 =1$ then
    Step 17: Add newline
    Step 18: If no pixels have changed, then exit while

2.2. MobileNet

In order to categorise photos [13], created the CNN-based model known as MobileNet. The main advantages of employing the MobileNet architecture are that it takes almost less computing effort than usual models, making it appropriate for use with mobile devices and personal computers with lesser processing capabilities. The main justification for the popularity of the MobileNet architecture is this. The MobileNet model is a sophisticated structure that includes a convolution layer that may be used to separate data that depends on two intelligent highlights that alternate between the accuracy and idleness of the border. You may use this layer to isolate the detail that is dependent on the two logical highlights. Utilizing the MobileNet concept to condense the network is advantageous. The MobileNet architecture is similarly effective despite having few standout features like Palmprint Recognition. A great amount of depth may be found in the MobileNet architecture. The fundamental structure is founded on a variety of layers of thought, each of which is a result of a variety of convolutions. These convolutions provide the idea of being a quantized design that examines a standard issue difficulty from every angle. The MobileNet model is a fundamental model that generates a convolution layer that may be used to identify data that is made up of several different sorts of data. The methodology behind Mobile Net is called depth analysis. The fundamental structure is predicated on a number of stacked abstract notion levels, each of which is made up of separate components in its own right. The convolutionary structure, which looks quite similar to the quantized structure, is what is used to evaluate the in-depth complexity of a common problem.

Pseudocode
Input: Braille character recognition_ Input Features
    Output: Classification of Braille text translation
    Function: MobileNet (Input features A, B)
    Step 1: Initialize Variables; min A, min B, max A, max B, A and B

min A =20; min B =20; max A = screenwidth – 20; max B = screenheight – 20

    Step 2: Draw Point
    Get (A, B)
    If (A >= (screenwidth - 30)); A = max A;
    If (B >= (screenheight - 30)); B =max B;
    Else
    If (A <= 20); A=min A;
    If (max B <= 20); B = min B;
    Circle (A, B);
    Step 3: Check swipe direction
    If event:swipe left to right
    Check image size
    If (ImageSize>64×64); Resize()
    SaveImage()
    Else
    Save Image ()
    Else event: swipe right to left
    Re-initialize all variables
    A.clear(); B.clear();
    Step 4: Pass Image to MobileNet Model

2.3. *Statistical analysis*

The output is created with Matlab software [9]. Training these datasets requires a display with a resolution of 1024x768 pixels (10th generation, i5, 12GB RAM, 500 GB HDD). In order to do a statistical analysis of the MobileNet and LSTM algorithms, we employ SPSS [15]. Means, standard deviations, and standard errors of means were computed by using SPSS to run an independent sample t test and then compare the two samples in Table 142.2. We have a dependent variable (accuracy) and two independent ones (MobileNet and LSTM).

3. Results

The MobileNet prediction model has a greater accuracy rate than the LSTM classification model, which has a rate of 94.33 in Table 142.3. The MobileNet classifier differs considerably from the LSTM classifier (test of independent samples, p 0.05). The performance measurements of the comparison between the MobileNet and LSTM classifiers are presented in Table 142.1. 05 percent, whereas the LSTM classification algorithm has a mean accuracy of 94. The MobileNet

prediction model has a greater accuracy rate than the LSTM classification model, which has a rate of 94.33. The MobileNet classifier has an accuracy rate of 98. The Proposed method has a mean accuracy of 98. 05 percent, whereas the LSTM classification algorithm has a mean accuracy of 94. 1529, and the LSTM algorithm has a value of 3.6574. The mean of MobileNet Standard Error is 0.

4. Discussion

Matlab is used to implement the programming language used by the system. Experiments are conducted to evaluate the outputs of the proposed model and achieve better outcomes by comparing the present LSTM technique to our new MobileNet method in terms of performance and accuracy in Table 142.1. The MobileNet method is therefore better to the

Table 142.1. The performance measurements of the comparison between the MobileNet and LSTM classifiers are presented in Table 142.1. The MobileNet classifier has an accuracy rate of 98.05, whereas the LSTM classification algorithm has a rating of 94.33. With a greater rate of accuracy, the MobileNet classifier surpasses the LSTM in predicting human emotion from speech signal

SI. No.	Test Size	Accuracy Rate	
		MobileNet	*LSTM*
1	Test1	96.63	93.50
2	Test2	96.94	93.53

LSTM method [20]. suggested an OCR based on a shape description of the alphabet, such as a histogram of origned gradients and geometric features. On one of the datasets, the work claims to have the greatest recognition rate, at 96.8%. In order to acquire gradient characteristics, the Sobel operator is used. Kawabe et al. [7] established a model that identifies the Japanese

Braille system necessary for the conversion of ancient Braille books to digital books. The model utilizes the Caffe and AlexNet frameworks in Figure 142.1. In addition to this, in the subsequent stage of multilingual mapping, we will expand the scope of the proposed method to include Braille contractions and abbreviations. We also intend to implement a system that will automatically recognize the language by determining the words and subwords that are utilized the most frequently in that language.

5. Conclusion

Using a novel MobileNet classifier, character-based braille recognition is implemented with remarkable efficiency. MobileNet trains the classifier using sounds in the pictures, which gives the model the ability to detect and categorise braille characters with a high degree of accuracy. This is in contrast to the LSTM image processing approaches that are commonly used. An examination of braille character recognition with a higher rate of accuracy finds that the MobileNet is 98.05% more accurate than the LSTM, which is only 94.33% correct. This suggests that the MobileNet is 98.05 percent superior to the LSTM. These outcomes validate the effectiveness of the proposed method for multilingual Braille translation in interacting with the visually impaired.

Abstract: Diabetic-Retinopathy (DR) is the leading reason of sightlessness in countries like India and the patients with diabetes risk having their eyesight impaired by diabetic retinopathy. The goal of this research is to examine the groundwork for improving Artificial Intelligence (AI) technology's ability to diagnose diabetic retinopathy. The research focuses on how various AI techniques might aid in the early detection of diabetic retinopathy, and how the prompt restoration of eyesight is more important than ever. The use of AI to healthcare is a developing field with potential for widespread screening and, eventually, more precise diagnosis. Complicated computing has made great strides in the area of pattern recognition by allowing for the construction of complicated connections based on input data and the subsequent comparison of these relationships to performance benchmarks. This paper is intended to design a novel algorithm to predict diabetic retinopathy in intense manner with proper accuracy metrics, in which the proposed methodology is called Improved Learning Scheme (ILS). This ILS methodology is an improved version of Convolutional Neural Network (CNN), the dense laye of the CNN model is altered by using an enhanced classification principle to alter the base algorithm for identifying the diabetic retinopathy disease in clear way with proper accuracy. The resulting scenario proves the accuracy of the proposed algorithm and its efficiency, in which the ILS provides 98.7% accuracy in prediction of diabetic retinopathy disease. For all, the proposed scheme is fine enough to predict the DR disease with proper classification results to realize the stage of affection in visual perception.

Keywords: Artificial intelligence (AI), diabetic retinopathy (DR), improved learning scheme, ILS, deep learning

1. Introduction

The stock market is a reliable and popular means to increase wealth. Individual investors' interest in the stock markets has grown in recent decades alongside the proliferation of information and communication technologies. As the stock market continues to attract more investors and businesses, many look for ways to anticipate how it will move in the future. This is a difficult issue brought on by a wide range of intricate variables. Although traditional techniques of optimization, such as the Nash equilibrium [1] and forecast methods, such as the Kalman-Filter [2], might be useful, AI can play a crucial role in this instance. Many academic articles focus on developing ML techniques for gauging AI's ability to forecast stock market performance. The majority of the time, the ML algorithms used in this context involves exploring data for patterns, quantifying investment risk, or making predictions about the future of investments. The most prevalent diabetic eye consequence is diabetic retinopathy and the patients struggling with diabetes along with retinopathy caused by diabetes typically get care that is disjointed, disorganized, and given in a piecemeal fashion, and this care is typically only available in tertiary care facilities that are both costly and energy intensive [3, 4]. To fill

these gaps in clinical care, innovative new models that include digital technologies are required.

The effects of diabetes mellitus on communities and healthcare systems are widespread. Having access to care as well as negative results persist, even in high-income settings, because the traditional diabetes mellitus care model, provided in various environments (community, primary, and specialist/tertiary), fails to adequately address the disease's multifaceted nature [5]. Therefore, novel, even revolutionary, new care models are required to address the condition and its consequences in a more comprehensive and coordinated manner. Preventing serious vision loss from diabetic retinopathy requires early identification; though, it can be difficult because the condition often shows no symptoms until it is too late to deliver effective medication. It is now a time-consuming and labor-intensive process to diagnose diabetic retinopathy by looking for illnesses associated with the abnormalities in the vascular system brought on by the condition that needs a doctor of ophthalmology or qualified physician to analyze and interpret computerized stereo fundus images of the retina. Rapid identification and determination using an automated system for diabetic retinopathy screening will aid in the management of diabetic retinopathy progression.

1.1. Statement of the Problem

- Inadequate population outcomes and challenges in keeping up with the rising burden of diabetes mellitus and associated consequences like diabetic retinopathy generally the results of the current care paradigms, which are fragmented and lack coordination across multiple settings.
- There is increasing demand to find ways to close these gaps, enhance patient identification and proper placement in eye care locations throughout healthcare networks, and broaden the scope of existing services.
- Leading artificial intelligence technologies for diabetic retinopathy diagnosis have received authorization from various health care organizations due to their replicable therapeutic and/or affordability in a variety of scenarios.
- Now, AI-based solutions are being described for determining which diabetic retinopathy patients are at the highest risk and therefore should be referred to tertiary care facilities, while allowing low-risk patients to continue to be screened in their local communities. This results in an enhanced patient flow within healthcare networks according to individual clinical needs.
- Patients more likely to react to therapies like anti-vascular endothelial development factor can be predicted, and possible clinical and/or patient variables for individualized therapy can be highlighted,
Figure 143.1. Examples of distinct types of microaneurysms.

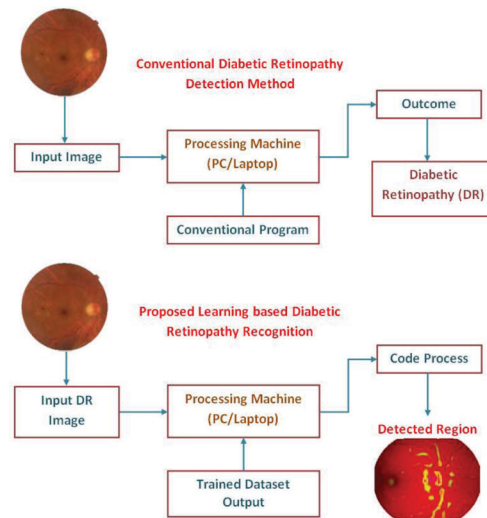
Source: Author.


Figure 143.2. Conventional and proposed learning assisted model processing for DR recognition process.

Source: Author.

thanks to the emergence of computerized techniques for diabetic retinal degeneration treatment.

Microaneurysms (MA), which appear as small red spots on the retina, are the earliest sign of diabetic retinopathy and are caused by the weakening of blood vessel architecture. This phenomena has a size less than 125 m and has sharp edges. As may be seen in the following figure, Figure 143.1, several researchers categorize

microaneurysms into six distinct subtypes. Adaptive Optics Scanning Laser-Ophthalmoscope (AOSLO) reflectance and Standard Fluorescence microscopy both revealed the various microaneurysms types [1].

1.2. Changes in Ophthalmology Applications based on Artificial Intelligence

Using Artificial Intelligence to fill up these gaps in patient care is one such novel approach. After more than 50+ years of development, AI systems have reached a level of performance that makes them ready for widespread clinical use across many branches of medical care. The transition from 'conventional' pattern recognition methods to the cutting-edge deep learning algorithms is a significant step forward. The new AI models are mathematically grounded in the use of gradient descent which reduces error in anticipated consequences, exceeding conventional regression methods for risk minimization, which includes the risk of 'over-fitting' an algorithm for prediction to training data, and thus making it easier to translate to practical applications. See how these two AI methods for identifying diabetic retinopathy in fundus images compare in the following figure, Figure 143.2. Classifying Optical-Coherence-Tomography (OCT) examines to prioritize referrals, predicting conversation of early to 'wet' stages of AMD, and tracing the development of diabetic retinal degeneration are just some of the many uses for algorithms that use deep learning and techniques in the field of ophthalmology [2].

The rest of the sections, Section-II illustrate the Related Study of the paper. Section-III illustrates the proposed methodology and the associated details of the article and the following Section-IV demonstrates the Results and Discussion part in detail. The Conclusion and Future Perspective of the paper is mentioned properly after the resulting portion.

2. Related Study

Diabetic retinopathy affects millions of people throughout the world and causes damage to the retina of the eye. The severity of the condition determines whether or not eyesight can be restored [6]. Retinal blood vessels and the tiny layers of the inside of the eye are both harmed. In order to prevent these complications, it is crucial to screen for DR as part of a regular screening regimen in order to identify very minor reasons of manual start. These diagnostic methods, however, are notoriously complex and costly. Among the special things this research has added [6] are: first, a comprehensive introduction to DR illness and standard diagnostic procedures. Secondly, multiple imaging methods and applications of deep neural networks in DR are shown. Thirdly, look into the different contexts and uses where

artificial intelligence has been used for DR detection. At long last, research options for exploring and providing efficient performance outcomes in diabetic retinopathy detection are brought to light by the study [6].

Recent years have seen a dramatic rise in the global prevalence of diabetes [7]. People of all ages are susceptible to it. Diabetic retinopathy is a disorder that causes vision loss in those who have had diabetes for a long period. Loss of eyesight and other consequences can be avoided with automatic detection utilizing modern technology for early detection [7]. As Deep Learning (DL) and other AI approaches have advanced, they have become the method of choice for creating DR detection systems. Following that, the report provides a list of some of the most popular data sets. Then, using certain standard metrics from computer vision tasks, we compare the studied approaches' performance [7].

If unchecked, diabetic retinopathy, which is brought on by diabetes, can cause complete blindness [8]. This research presents an original automated method for DR detection. To better show up the lesions, Contrast-Limited-Adaptive-Histogram Equalization was applied to the raw fundus images before analysis. We first utilized a PCNN to extract features, and then we sent those features into an ELM for further processing method to classify DR. The PCNN architecture employs fewer parameters and layers than the comparable CNN architecture, which reduces the time needed to extract unique features. The proposed method [8] achieved accuracies of 91.78 and 97.27 percent, respectively, for the two datasets given. However, the study also found that the suggested framework showed stability for both bigger and smaller datasets, as well as balanced and unbalanced datasets, which was an interesting finding in its own right. In addition, the proposed method outperformed the state-of-the-art models in terms of classifier performance metrics, model parameters and layers, and prediction time, which would be of great use to doctors in correctly detecting the DR [8].

Diabetic retinopathy is a disease of the retina that occurs in patients with diabetes [9]. Damage to the blood vessels of the eyes, which can lead to blindness, occurs when blood sugar levels are too high. The microaneurysms and exudates that are characteristic of diabetic retinopathy are the red and yellow patches on the retina, respectively. Based on the finding that drips and tiny vessels may be detected early on in the course of diabetic retinopathy, this study proposes a straightforward and effective treatment method. The empirical study takes use of real-time data sets of colored fundus images captured by cameras as well as publically available datasets. The proposed research uses drips and micro-aneurysms in fundus images to categorize diabetic retinopathy as moderate, severe, or mild. An automated method [9] based on image

processing, feature extraction, and machine learning models has been proposed for accurately predicting the presence of drips as well as micro aneurysms for grading purposes. The research may be broadly classified into two subfields: fluids and micro-aneurysms. Exudates are assessed according to their distance from the macula, while the number of micro aneurysms is used to determine a patient's overall grade. KNN and SVM had the best accuracy (92.1% and 99.9%, respectively) for predicting disease severity levels based on exudates, whereas decision tree has the highest accuracy (99.9%) based on micro aneurysms [9].

Diabetic retinopathy is caused mostly by diabetes [10]. Long-term uncontrolled diabetic retinopathy causes complete blindness. Preventing DR is a difficult and important endeavor now since it lowers the total risk of blindness. The use of machine learning and deep learning can be helpful in the detection and diagnosis of DR. In this study, we suggest a novel approach using Machine Learning and Deep Learning. Kaggle dataset is used for both training and testing in this suggested system. There are a total of 3662 photos utilized; 2744 are used toward teaching the model, while the remaining 546 are put toward validating it. The results show that the CNN Classifier outperforms the SVM classifier [10] in detecting diabetic retinopathy.

3. Methodology

The lack of insulin in diabetics causes a rise in blood glucose levels, the hallmark symptom of the disease. Diabetes causes damage to the eyes, heart, nerves, and kidneys. Diabetic retinopathy is a serious complication. Mechanized approaches for recognizing diabetic retinopathy are more competent than manual analysis and may be easily adjusted to save time and money. Computer-assisted medical diagnosis is performed using the Deep Learning method. In this research, we want to take the guesswork out of diagnosing and treating early-stage diabetic retinopathy. With the use of AI and Deep Learning, eye specialists can detect blindness in its early stages. This paper introduced a new methodology called Improved Learning Scheme (ILS), in which it is accumulated from CNN logics and the working principle of the proposed algorithm is illustrated clearly in the following architecture diagram, Figure 143.3.

A collection of pixels is used to capture the image and the important characteristics are extracted from the dataset after it has been rescaled and preprocessed using certain filters, and the pictures have been labeled with their class-names. For example, shear angle, horizontal flip, and vertical flip are all part of the preprocessing phase. Data augmentation, dataset shuffle, and train/test data separation. Generating data for use in a variety of contexts, including training, testing, and validation. Using convolutional logic and an identity block, we construct a deep learning model dubbed ILS. Gathering along with training the model follow the identity block. To avoid the over fitting problem, we used early stopping to terminate training after a predetermined number of epochs if the loss of validation was still increasing. We analyzed the classification by plotting the confusion matrix and seeing the findings from the trained model's evaluation. The user interface will update to reflect the patient's diagnosis.

4. Results and Discussions

The dataset used in the proposed procedure was collected from the Kaggle open source and consists of fundus photos captured by technicians with the pupil dilated. The proposed algorithm Improved Learning Scheme (ILS) accumulates the data from dataset and trains those images properly by using the learning model. Once the images are trained that will be properly tested by using some sample sets. The following figure illustrates the quantity of images presented into the input dataset, in which it is portrayed by using the graphical representation over the figure, Figure 143.4. The same is depicted over the following table, Table 143.1 [11].

The following figure, Figure 143.5 portrays the accuracy estimations of the proposed learning model ILS, in which the accuracy is measured based on the number of images accumulated from dataset for training. The following figure, Figure 143.6 portrays the loss estimations of the proposed learning model ILS, in which the loss is measured based on the number of images used for training.

5. Conclusion and Future Scope

This system can recognize diabetes using an image-based deep learning method called ILS, and it may one day be used as a tool for diagnosing the disease. This method has the ability to learn from raw pixels and make use of the countless images processed for screening by physicians' interpretations. These models' substantial variability as well as small bias suggests that ILS might be used to diagnose conditions beyond diabetes. Visualizations of the suggested method's features reveal that the classification

signals are in a spot where a human viewer can readily take them in. Macroscopic features at a scale beyond the capability of existing model designs for training and validation can be seen in retinal images of individuals with moderate and severe diabetes. Future work can involve training the model in the system, which will increase the amount of data handled and, in turn, the quality of the forecast. As the number of people with type 2 diabetes rises, the prevalence of significant complications including diabetic retinopathy and diabetic nephropathy also rises. About a third, or about 285 million people, have diabetes and are affected by diabetic retinopathy that are diabetic, and one-third of them have advanced vision-threatening retinopathy.

Abstract: A malignancy of the skin is a spot on the skin that has developed a growth or looks different from the surrounding skin. Most are completely safe to ignore, but others may be early indicators of skin cancer. Early diagnosis in dermoscopic images of melanoma, the deadliest type of skin cancer, is vital and resulting in a rise in the patient's overall survival rate. A lack of contrast between cancers and the epidermis visual similarities among melanoma with non melanoma inflammation, and other factors make correct detection of melanoma difficult. Therefore, accurate and efficient pathologists would benefit greatly from having access to dependable automated identification of skin cancers. However, the current method utilized to identify cancer is laborious. The use of machines to aid in cancer diagnosis is not only more accurate, but also more time efficient. Deep learning refers to a type of machine learning that attempts to simulate the way the human brain processes information in order to make decisions. Correct and accurate skin cancer screening is becoming increasingly important. Recent developments in deep learning make it an ideal tool for automated detection, which is of great assistance to pathologists with regard in both the efficiency of its operations and its precision. This work presents the Advanced Learning based Prediction Principle (ALPP), an energetic artificial intelligence assisted architecture tailored for the timely assessment of skin cancer. Several cutting-edge deep and machine learning models are employed in this suggested methodology. The parameters are analyzed, and cutting-edge methods are used to overcome obstacles in segmentation of skin lesions and classifications. The suggested model has a 96.8% success rate in differentiating between benign and cancerous.

Keywords: ALPP, advanced prediction principle, classification, segmentation, deep learning, melanoma detection, skin cancer, skin lesions

1. Introduction

When left untreated, Melanoma, the deadliest type of cancer of the skin, in which it can expand to other organs and about 75% of all cases of skin cancer end in death because of this. A larger percentage of patients can be expected to survive if the disease is detected and treated at an earlier stage as well as around 60% of cases of melanoma may be diagnosed clinically with the naked eye. The subject of artificial intelligence in association with learning schemes has seen a lot of growth and development recently, and it has been getting a lot of traction. The efficiency and precision of the pathologists can be improved by the use of a reliable atomic method for the detection of melanoma. This improves in identification by improving the visual characteristics of the skin cancer. This framework is capable of performing a reliable lesion classification in an efficient manner, and it can classify lesions as

either benign or malignant. The deep learning model directly and automatically categorizes the set of input, which may include pictures in addition to text and other types of data. The neural network design that underpins deep learning consists of several layers, and it is taught using a big dataset. The ALPP that was suggested is currently being regarded the architecture of choice for image classification in a number of different applications, particularly those that deal with the classification of medical images. Through repeated training of the model on incorrectly categorized instances, in which it is compatible to the human recognition process, the goal of this technique is to enhance the effectiveness of the framework.

However, melanoma detection through deep learning approaches has numerous obstacles. Here are just a few of them: Differences in dermatological circumstances, such as the coloration of the skin and the presence of hair around the patch, and subtle variances in contrast between epidermis as well as lesions can help distinguish melanoma spots from benign ones in Table 144.1. As a result, the melanoma spot will have its own unique set of features, coloring, and so on. In many

contexts, segmentation is an essential first step in the classification process [4]. The results of an extensive research of algorithms for automating the differentiation of lesions of the skin are in. The segmentation of the skin lesion is a necessary step for the majority of the categorization methods. It has been shown that precise segmentation can improve the accuracy of future lesion classification and a great deal of research has been done in order to create reliable segmentation outcomes for lesions. For the purpose of the segmentation of skin lesions, a number of researchers presented an unsupervised technique that they called Independent Histogram Pursuit. The precision of categorization is improved through segmentation. There have been a lot of research efforts devoted to getting good segmentation outcomes.

Features for melanoma detection may then be retrieved from the segmentation results. Despite extensive research, there is still much room for performance enhancement in the segmentation and categorization of skin lesions. Facilitating the use of digital skin imaging to minimize melanoma-related mortality is the primary goal of the International Skin Imaging Collaboration's Melanoma Project. Since 2016, they have been building and refining an image database of skin. It's a repository that anybody may use for free to help create and test out automated diagnostic tools. In terms of dermoscopy feature extraction, they have raised the bar [5].

The accompanying figure, Figure 144.2, provides an illustration of several types of skin cancer image samples obtained from the dataset for processing. These samples were taken with the intention of highlighting the region of the figure that contains cancer in a clear manner.

Table 144.1. Wide range of skin cancer types and its spreading ratio [1]

S. No.	Types of Skin Cancer	Spread Ratio
1.	Cancers of the Squamous-Cell and Others	17%
2.	Merkel-Cell-Carcinoma	2%
3.	Dermatofibrosarcoma-Protuberans	1%
4.	Basal Cell Carcinoma	70%
5.	Melanoma	10%

1.1. Major contributions

The following is a description of the most important contribution made by this paper:

(i) The currently available methods of deep learning typically make use of two networks to carry both tissue damage segmentation as well as classification in a separate fashion. In this study, we introduced a framework that is comprised of a completely upgraded learning model termed the Advanced Learning based Prediction Principle. Within this framework, it is utilized to handle lesion segmentation as well as lesion classification. The suggested structure will hereafter be referred to as the ALPP in Figure 144.1.

(ii) In order to solve the issue of dermoscopic feature extraction, we created a deep learning-based system and gave it the name ALPP. The results of our experiments show that our framework offers competitive performance, and to the best of our expertise, we have no conscious of any earlier work that has been offered for this purpose. As a result, it is possible that this study will serve as the standard for the subsequent research that is relevant to this subject.

(iii) We performed an in-depth investigation of the suggested deep learning structures in a variety of aspects, such as the capabilities of networks with varying depths and the affects generated by the addition of a variety of components. This study offers helpful instructions for the creation of deep learning networks to be used in medical research that is linked to this topic.

In recent years, the Deep Learning approach has demonstrated remarkable performance in a variety of computer aided diagnosis applications and has achieved significant success in a number of prediction-based applications. ALPP outperformed experienced medical professionals in terms of accuracy and it is used to classify cancers according to high-level characteristics instead of the traditional technique that incorporates low level dermoscopic apparent information but necessitate an earlier classification step to extract these characteristics and the proposed ALPP superior to highly authorized physicians in terms of how quickly it classified skin lesions.

2. Related Study

Because of the high death rate, high treatment costs, and quick progression of malignant cancer of the skin, there is an increasing demand for early detection of skin cancer [6]. This is due to the rapid expansion of skin cancer caused by melanoma. The diagnosis of cancerous cells in the skin was traditionally performed by hand, and the majority of cases need for a protracted treatment. The high misclassification rate along with inadequate accuracy that currently plague skin cancer detection methods is the primary issue at hand. This research presents a method that uses methods of deep learning to identify cancer from photographs of the skin. The study in question makes use of a model that is based on a CNN and has six layers, including hidden layers. The issue of inadequate precision is handled [6] by utilizing the regularization approach, and the convolution method is utilized for the purpose of feature selection. Both model parameter tuning and hyper parameter tuning are carried out in order to achieve the goal of improving the accuracy of the model. The research makes use of a dataset that is accessible to the public and which comprises photographs of cancer as well as normal occurrences. Data gathering, preprocessing, data cleaning, data visualization, and model creation are the primary stages of this task, which are referred to together as step 6. In the conclusion, a comparison study using the most recent and cutting-edge methods is carried out. When compared to the strategies that are considered to be state of the art, the suggested model attained a decent precision of 88% on the HAM dataset [6].

Skin cancer is regarded as one of the most lethal types of the disease [7]. Dermatological illnesses are one of the most urgent medical concerns of the 21st century. This is mostly because diagnosing these conditions may be extremely challenging and costly, not to mention fraught with human subjectivity and complications. When it comes to potentially fatal disorders such as melanoma, early identification is absolutely necessary for determining the patient's chance of making a full recovery. Skin cancer is caused when DNA breaks occur in skin cells and they are not repaired. This leads to genetic errors or mutations, which can lead to the disease. Because early stages of skin cancer are more amenable to treatment, and because skin cancer has a propensity to progressively spread to other regions of the body, it is important to diagnose it at its earliest stages [7]. Because of the increased prevalence of cases, the high fatality rate, and the high cost of medical treatments, early diagnosis of skin cancer signs is absolutely required. In light of the magnitude of these challenges, researchers have developed a variety of early. Numerous studies [7] have been conducted in order to investigate the automatic categorization of melanoma photos through the utilization of machine learning and computational vision approaches. Despite the fact that these studies produce encouraging results, the classification efficacy of traditional machine learning as well as computer vision methods of detection for skin cancer is significantly impacted by the segmentation of the lesion on the skin and the features identified for the categorization approach. This is the case even though these factors have a significant impact on the

classification performance. It is possible to differentiate between both malignant and benign forms of skin cancer based on the features of the lesion, which might include symmetry, color, size, and shape, amongst others. The use of automated procedures is thought by specialists to be something that will help with early diagnosis, particularly in situations when a collection of photographs has a variety of diagnoses. This study offers a comprehensive look at the examination of deep learning strategies for the early diagnosis of skin cancer. Our model development process consists of three stages: the first is data gathering and augmentation; the second is model design; and the third is prediction. Image processing technologies, combined with the Inception Version 3 approach, were utilized here in order to enhance the structure and bring the level of accuracy up to 84% [7].

Deep convolutional neural network models [8] have been extensively researched for the purpose of diagnosing skin diseases, and some of these models have reached diagnostic results that are on par with or even better than those produced by dermatologists. However, the limited quantity and uneven distribution of data in publicly available skin lesion datasets provide a barrier to the widespread application of DCNN in the diagnosis of skin diseases. In this research, a unique technique for determining the type of skin lesions based on a single model is proposed. The datasets used are both tiny and unbalanced. To begin, a number of distinct deep convolutional neural networks (DCNNs) are trained on a variety of disparate and relatively small datasets [8].

Melanoma screening should always include short-term monitoring of lesion changes [9], since this is a clinical recommendation that has received widespread acceptance. After three months, if there has been a substantial change in a melanocytic lesion, the lesion will be removed to rule out the presence of melanoma. Nevertheless, the decision to make a change or not to make a change is highly dependent on the experience and prejudice of individual physicians, which is a subjective factor. This is the first time that a unique technique based on deep learning has been devised for automatically identifying short-term disease modifications during melanoma screening. The method was developed in this publication. In order to assess the implemented strategy [9], an internal dataset consisting of one thousand different pairs of lesion photos that were captured within a brief period of time at a clinical melanoma center was developed. [9] The findings of experiments performed on a large dataset that is the first of its type show that the suggested approach shows promise in detecting the short-term change in lesion status for the purpose of objective melanoma screening.

In this study [10], a complete analysis of skin cancer segmentation as well as classification utilizing computer vision and deep learning approaches has been

given. These techniques were used to analyze images of skin cancer. Melanoma is the most dangerous kind of skin cancer, and it is the only one that can result in death if it is not diagnosed and treated while it is in its early stages. Melanocytes, which are cells that create melanin, are to blame for melanoma [10]. Melanoma can be discovered in any region of the body, however it most commonly manifests itself on the skin. If you minimize your skin's exposure to UV radiation, you may significantly cut your risk of developing this condition, which is mostly brought on by sun exposure. If early warning symptoms of melanoma are discovered, it may be possible to stop the cancer from spreading to other areas of the body. In order to diagnose malignant melanoma, dermatologists evaluate photographs of skin lesions using their knowledge and years of experience in the field. This process takes a lot of time and there is room for error because it involves people. It is possible to eliminate the inaccuracy by using automatic techniques for separation or identification through the utilization of computer vision and methods of deep learning. It was discovered that deep learning could be used to segment or identify medical images, and that this method was both effective and more accurate than human-level methods [10]. When it comes to dermoscopy, a broad variety of algorithms for deep learning and machine learning are used for improved melanoma classification, segmentation, and analysis. Deep neural networks are used to train these algorithms on a huge number of photos of melanoma, some of which are benign and some of which are malignant. The images are annotated by medical professionals. The identification of melanomas in the medical literature makes use of a significant number of datasets. ISIC preserve, HAM10K, PH2 database, MED-NODE database and DermIS picture library are only a few examples of widely utilized datasets. The region under a curve, specificity, sensitivity and accuracy have been the most popular assessment matrices that authors have employed for the models [10].

3. Methodology

In the vast realms of computational imaging and artificial intelligence, segmentation of images is among the highest priority topics. It's used for a wide range of things, from medical image analysis to robotics perception to augmented reality to photo compression and beyond. One of the most crucial issues in these disciplines is image segmentation. Segmentation is the process of dividing a visual source into smaller pieces for the sake of analysis. Out of the numerous distinct sorts of regions and entities split by the networks, only the most important are selected for investigation. There are many different kinds of pixels in the image, so we need to sort them into groups based on their

shared characteristics. A bounding-box method, in which a rectangular shape is created around the region of interest, or pixel-wise labeling, in which different classes are highlighted using different color schemes, are common methods for achieving this goal. Our goal is to use a segmentation technique to remove the skin from a picture, highlighting just the mole. The process involves peeling off the skin. We are using the melanoma dataset that includes several types of images and masks, to complete the segmentation procedure. The mask represents the input image's truth; it specifies, according to the individual threshold, which pixels is part of a particular class particle and which ones are excluded. The mask is binary, meaning that each pixel may only take on the values 0 or 1, in regard to the numbers that can be portrayed through them. If the pixel's value is 0, then it is not an actual mole, and if it is 1, then it is a mole. This seemingly black-and-white grayscale image really contains just a single channel. The following figure, Figure 144.3 show that the image acquired from the dataset and the mask position marked over the respective image in clear manner.

Before beginning the training process, the photos that would be used to train the deep learning technique were first standardized. This assists in bringing it under an appropriate threshold range and it also helps lower the skewness thereby helping the system learn more effectively and quicker. We computed the average value of a pixel as well as the deviation from it for each of three distinct color mediums, including Red, Green and Blue (RGB). The following table, Table 143.2 illustrates the value specifications of the RGB color value metrics in clear manner and the figure, Figure 144.4 depicts the same in graphical format. The results were normalized with the corresponding values and the following equation, equation (1) was utilized for the normalization process.

$$Md^{Out} \rightarrow \frac{Ip - Mv}{Sd} \tag{1}$$

Where Md^{Out} denotes the Melanoma Detection output index, Ip indicates the Input, Mv indicates the Mean Value and Sd indicates the Standard Deviation.

4. Results and Discussions

In this research, dermoscopic pictures were fed into an Advanced Learning based Prediction Principle (ALPP) architecture to extract deep features for the purpose of classifying melanoma into cancerous and benign types. The goal was to determine which types of melanoma are more likely to spread. Two distinct stages are involved in the process of arriving at a diagnosis of a skin illness. Collecting and preparing the information, as well as the training and testing phases of the ALPP model that is being constructed are all included in Phase I. The second phase involves the actual installation of the system and the display of the results. We merged at least six distinct databases since we knew that the database was one of the criteria that determined how accurate our predictions would be. These databases were compiled by a variety of medical professionals, researchers, medical students, pathologists, and competitions. Additionally, the manual segmentation, the clinical diagnosis of the skin lesion, and the identification of several other essential dermoscopic criteria are all available for each picture in the database. This information may be accessed manually. These dermoscopic parameters include an analysis of the asymmetry of the lesion, as well as the recognition of colors and a number of distinct structures, including pigment networks, spots, globules, streaks, regression zones, and blue-white veil. Images obtained from the International Skin Imaging Collaboration 2018 Competition, the collection of data was split into a training set and a testing set with an 8:2 split respectively. A
Figure 144.4. RGB color values utilized for processing.

Source: Author.

portion of the images in the collection are subjected to preprocessing, which consists of rescaling the images and labeling each picture individually. The class 0 conditions are considered to be benign, whereas the class 1 conditions are considered to be cancerous.

The accuracy estimations of the proposed ALPP learning model are depicted in Figure 144.5, where the accuracy is calculated based on the number of images gathered from the dataset for training. The number of images collected for training only shows the output accuracy in a precise manner; if the quantity of images is low, the output accuracy is obviously low, and if the quantity of images is big, the accuracy is obviously high. Similarly, Figure 144.6 depicts the validation loss perception of the proposed learning model ALPP, where the loss is assessed based on the number of photos used to train the model.

5. Conclusion and Future Scope

In this research, we addressed the three fundamental issues of skin cancer image processing by proposing a deep learning framework, in which it is named as an Advanced Learning based Prediction Principle (ALPP). These challenges include lesion segmentation, dermoscopic feature extraction, and lesion classification. It is envisaged that ALPP would address both the segmentation and classification of the lesion concurrently. When producing the segmentation outcome and the coarse classification result, the suggested model goes through training with several distinct training sets, which are then used. The suggested approach takes into account the significance of each pixel while making a determination about the categorization of lesions, and the preliminary classification is then improved based on the distance map that is produced by ALPP. The proposed model if further enhanced by means of integrating some classification logics along with that to make the accuracy better as well as refine the proposed work in different levels of classification scenarios.

145 A study on flexible behavior of ultra-high-performance fiber-reinforced concrete composite panels

Swati Agrawal[1,a] and Cherry[2]

[1]Assistant Professor, Department of Civil Engineering, Kalinga University, Raipur, India
[2]Department of Civil Engineering, Kalinga University, Raipur, India

Abstract: A novel material in the realm of bridge engineering is ultrahigh-performance fiber-reinforced concrete. This new material, with its improved mechanical properties, allowed contemporary bridges to have longer spans and lower structural self-weight. In order to provide trustworthy design guidelines for UHPFRC buildings, a number of experiments must be carried out. The goal of this research is to examine the performance of a box-celled panel system made by inserting anchor screws into galvanized steel roofing profiled sheets and casting UHPFRC (ultra-high-performance fiber-reinforced concrete). Six specimens are produced by casting two panels for each of the three reinforcement-based design modifications that are examined. The structural responses of the variations under three-point flexure as one-way panels are investigated experimentally for both positive and negative bending moment capacities. Experiments showed that the steel profile might fail by shear, completely delaminating, or flexuring with significantly higher ductility and post-failure load capacity. These results were also avoided using anchor screws. The suggested system's optimal performance was highlighted by analysis based on test results, which demonstrated compliance with several design requirements based on upper limits for combined loading actions and allowable deflections.

Keywords: Ultrahigh-performance fiber-reinforced concrete, Box-celled panel, steel sheets, flexure capacity, ductility

1. Introduction

The primary concept is the application of UHPFRC in the construction of bridges located in areas with high mechanical stress [13], high seismic zones [14], and harsh environmental conditions [15]. The benefits of the girder system translate to the idea of box-cell panels and are amplified when used to roofing and cladding components that are subject to buckling, torsion, and uplift [2, 3]. Because the top and bottom flanges bear the majority of the flexural compression and tension loads, the trapezoidal void does not affect the sectional capacity for either positive or negative bending, and the box-cell panel system remains structurally efficient despite its presence [4]. Nevertheless, because of the properties of UHPC under tension, the failure mechanism in flexure in both positive as well as negative bending force is brittle. It is necessary to look into the creation of novel composite panel systems using box cells since there is a dearth of study on the use of alternative materials in pre-cast composite panel systems. The use of steel

fibers in UHPC to produce ultra-high-performance fiber-reinforced concrete is one notable achievement. The brittleness of UHPC under tension is improved by the inclusion of steel fibers, which also greatly increases ductility and enhances strain hardening properties [20]. Steel or fiber-reinforced polymers are typically used to reinforce composite panels made of precast concrete in areas that experience high compressive and tensile stresses. Nevertheless, minimum cover requirements to avoid corrosion and bond failure restrict the optimal design of composite panel layers [6]. Steel sheets are useful in the construction of concrete composite panels because they act as a persistent framework for casting in place and as tensile reinforcement without the need for bolstering inside the cementitious layers [7, 8].

2. Literature Review

Chen et al. 2021 demonstrated that after being exposed to heat, UHPC beams with hybrid polypropylene and

steel fibers exhibit better flexural performance. Even at 500°C, the beams didn't spall following pre-drying treatment [26]. High temperatures caused the polypropylene fiber to melt, increasing the UHPC matrix's permeability and releasing water vapor, as seen by SEM. There was a greater rigidity and less deflection under load in the post-cracking stage. In comparison to HSC specimens, overall residual peak load ratios remained as high as 0.94, and the ductility was superior. Spill resistance can also be increased by lowering moisture content. Investigations on the flexural behavior of UHPC beams under elevated temperatures are warranted.

Qiu et al. 2020 examined the reinforced UHPC low-profile T-beams' static bending performance and developed a formula to estimate their ultimate capacity. The findings indicate that there are three phases to the T-beams' flexural behavior: elastic, yield strengthening, and crack formation. The study also discovered that while raising the reinforcement ratio has minimal effect on the cracking load, it can enhance pre- and post-cracking stiffness as well as bending capacity. The bending performance of straight fibers is mostly insensitive to the length-to-diameter ratio. A formula that takes the UHPC's tensile characteristics into account was proposed for determining the ultimate loading capacity.

Weina Meng and Kamal H. Khayat 2016 studied the flexural behavior of ultra-high-performance concrete (UHPC) panels strengthened with GFRP grids using both experimental and computational methods. Bridge columns or walls can be constructed using the panels as permanent formwork elements. In addition to testing the flexural performance of panels with various reinforcement configurations in three-point bending tests, the mechanical characteristics of GFRP grids and UHPC were assessed. UHPC panels' flexural performance was greatly improved by the GFRP grids. In order to anticipate post-fracture behaviors, a three-dimensional nonlinear finite element model was created using ABAQUS and included the concrete damage plasticity model. In order to improve crack resistance and service life, the suggested GFRP-UHPC panel system holds promise for lightweight, high-performance permanent formwork that may be utilized in the rapid building of vital infrastructures [27].

Al-Osta et al. 2017 examined how reinforced concrete beams reinforced with UHPFRC behaved flexurally. Tests on bond strength demonstrate that UHPFRC has strong bonding qualities even in the absence of concrete substrate surface preparation. In a slant shear stress test, concrete substrates with a surface roughened by sandblasting and new UHPFRC cast around it exhibited greater bond strength. In addition to decreasing deformities under applied loads and helping to enhance cracking load, UHPFRC strengthening also raised the rigidity of the beams made of concrete during service conditions and postponed and spread crack propagation. The reinforced beams exhibited monolithic behavior; neither of the two jacketing preparation processes showed signs of debonding. For any strengthening configuration, the analytical model provides a highly accurate prediction of the reinforced beams' moment capacity.

Luaay Hussein and Lamya Amleh 2015 examined the UHPFRC-NSC/HSC composite beams' flexural and shear properties. According to the results, flexural capacity is greatly increased by 54% and 90%, respectively, by incorporating a UHPFRC layer at the bottom of the NSC prism. Both the ultimate shear capacity of the composite beams and the bond strength between the NSC/HSC and UHPFRC layers are greater than those of the NSC/HSC beams. In contrast to NSC/HSC beams, the composite beams show great ductility. Regarding UHPFRC's role in shear strengthening, the suggested shear model, Vu, offers encouraging insights.

3. Materials and Methods

3.1. UHPFRC

For the current investigation, an altered version of a UHPFRC mix design was employed; Table 145.1 displays the mix proportions. To increase compressive strength and ductility, steel fibers with a diameter of 0.2 mm and a length of 12 mm were added to the concrete mixture. The fibers' ultimate strength (fult) is 2675 MPa, and their nominal Young's modulus (Es) is 225 GPa. Nine cylinders measuring 100 mm in diameter and 200 mm in height were cast, cured, and tested to determine the UHPFRC mix's Young's modulus and compressive strength. It was found that an average compressive strength after 28 days was 115.5 MPa, with a 5.9 MPa mean deviation and a 0.061 coefficient of variation.

Table 145.1. Mix proportions

Materials	Mix proportions
Cement	1
Silica Fume	0.23
Sand	1
Water	0.18
Superplasticiser	0.043
Steel fibre	0.18
w/c ratio	0.2

Source: Author.

3.2. Test specimen

To evaluate the box-cell panels' structural performance in both positive and negative bend angles, six UHPFRC panels with different reinforcement configurations and dimensions of 1500 x 700 x 70 mm were cast and subjected to one way bending tests. The change in reinforcing arrangement and loading direction for the tests conducted is shown in Table 145.2. In the initial test specimen, S1A, 6 longitudinal PFRP (polypropylene fiber reinforced polymer) bars with an dia. of 7 mm were positioned in the panel's top layer to obtain a ratio of reinforcement of 0.53% of the panel's cross-sectional area. Contrary to specimen S1-A, the other specimen, S1-B, had a steel face instead of a concrete face under stress. This was done in order to determine the panel system's 3-point bending capability in terms of hogging and sagging moments. The reinforcement ratio of the third and fourth examples, S2-A and S2-B, was 1.30% despite their similarity to specimens S1-A and S1-B. This was due to the insertion of nine longitudinal steel bars, each with an 7 mm diameter, which were positioned in the bottom UHPFRC layer within the steel profile channel troughs. S3-A and S3-B, the fifth and sixth examples, are the same as S2-A and S2-B, except they have steel reinforcement instead of PFRP. Similar to example S1-A, specimens S2-A and S3-A are put onto the concrete face, while specimens S2-B and S3-B are loaded onto the steel face. Due to its ability to be positioned inside the section layers and offer sufficient transparent cover, the reinforcement's size was selected.

3.3. Test setup

In order to determine the tensile behavior of UHPFRC, dog bone samples were subjected to direct tension after being horizontally cast. One of the dog bone samples is a shanked segment measuring 325 mm in length and 120 mm by 120 mm in cross-section. The ends are tapered to yield 604.8 mm specimen length and square ends measuring 208.6 mm by 208.6 mm.

The samples underwent displacement control testing, with a rate increase to 0.05 mm/s till failure from 0.02 mm / s to 2.5 mm displacement. In order to quantify the displacement, four LVDTs were fastened to sliding rods that were affixed to the sample. In order to prevent stress concentrations at the bulbed ends, the specimens were set up in a specialty test rig. Gypsum paste was applied to the bulbed ends' curved surfaces to provide uniform contact between the specimen and the test jaws throughout the loading process. 3.93 MPa was found to be the mean yield strength, with a 0.123 frequency of variation and a 0.32 MPa mean deviation. Along with the UHPFRC's load-deformation and stress-crack width correlations, there is also an average tensile stress-strain connection.

The calculation of strains included dividing the average LVDT data throughout the length of the specimen shank. Using the following equation, crack widths were calculated by combining the material parameters obtained from the compressive strength test results with the LVDT measurements:

$$s_{Cr} = \frac{PL}{\varepsilon_C A} - \Delta_{total}$$

It was hypothesized that the combination of elastic and inelastic material contributed to the dog-bone specimen's overall deformation, with the inelastic component being linked to the cracking breadth. Previous studies on strain and fracture width computations for UHPFRC specimens in tension have confirmed this assumption.

4. Result and Discussion

4.1. Load-deflection behavior

Figure 145.1 illustrates the load-deflection relationships that were tested for UHPFRC panels that were loaded onto the concrete face. The experimental data shows that, once cracking and delamination started, all three objects' stiffness decreased from their equal levels during the phase of linear elastic. Because of the tensile area's steel reinforcing bars, sample S2-A

Table 145.2. Test matrix for UHPFRC panels

Specimen	Face of loading	Placement of reinforcement		Ratio of reinforcement, ρs (%)
		Bottom layer	Top layer	
S1-A	UHPFRC		PFRP bar	0.53
S1-B	Steel Sheet		PFRP bar	0.53
S2-A	UHPFRC	Steel rebar	PFRP bar	1.30
S2-B	Steel Sheet	Steel rebar	PFRP bar	1.30
S3-A	UHPFRC	PFRP bar	PFRP bar	1.30
S3-B	Steel Sheet	PFRP bar	PFRP bar	1.30

Source: Author.

displayed the greatest stiffness during the linear elastic phase, whereas reference specimen S1-A displayed nonlinear behavior considerably sooner. At the highest load, panel specimen S1-A deflected 41 mm and achieved a peak load of 48.6 kN. Around 25 kN of applied force was sufficient to cause the screw anchors to separate from the foam and UHPFRC, indicating a satisfactory phase of linear elastic stiffness. This was clear from the space b/w the bottom layer of UHPFRC and the steel profile that was discovered during the post-test inspection. With the increasing applied load, a tensile fracture in the UHPFRC also developed and deepened; however, because of the fibers inside the matrix of concrete, the ductility after peak was notable and shown in Figure 145.1. The abrupt decrease in the panel's ability to carry loads was indicative of a rupture in the reinforcement, as demonstrated by its post-peak behavior. When the structure failed, a major steel sheet fracturing under tension occurred at the mid-span, at the loading area, a crushing of concrete was discovered, and the tensile crack spread to the top face.

At the highest load, panel specimen S1-B deflected 36.1 mm and achieved a peak load of 93.6 kN. In comparison to specimen S1-A, the panel showed a notable linear-elastic stiffness; the first indications of nonlinear behavior appeared with an applied force of 75 kN. Due to high strain rupturing the steel rebars in the area of tension before a progressive drop to failure, a considerable loss of load-carrying capacity occurred when reaching the peak load. This specimen showed a greater degree of debonding between the UHPFRC and the steel profiled sheet, which contributed to the panel's collapse. Similar to specimen S1-A, the UHPFRC experienced a tensile crack formation when the applied load increased. Nevertheless, the crack's propagation across the panel section was restricted to the tensile area, indicating that the axis of neutrality did not considerably elevate along the section overview. The combination of the steel sheet's tensile fracture, the foam's slight crushing, the concrete's top face minor crushing, and the UHPFRC's significant debonding from the profiled sheet caused specimen S1-B to fail.

At the highest load, panel specimen S3-A deflected 51 mm and achieved a peak load of 85 kN. When compared to panel specimen S1-B, the panel's mid-span deflection at failure was 43% larger, indicating substantial ductility in the pre-peak period. Two noteworthy characteristics were observed, though: the section's significant load-carrying capacity after collapse and a rapid and significant drop in the capacity to handle loads during peak load. The longitudinal PFRP bars' rupture in the tensile zone is the cause of the notable reduction in load-carrying capacity. But for the whole test (15 kN), the applied load upon rupture was maintained. More importantly, debonding failure was limited to the post-peak period, indicating the panel's strong shear capability. Nevertheless, the panel's post-peak capacity was not lowered as a result of the degree of debonding or the little crushing of the UHPFRC.

Figure 145.2 displays the experimental relationships between load and deflection for the UHPFRC panels that were placed on the steel side. The three panels exhibit almost comparable load-deflection behavior under three-point bending, as demonstrated by the experimental results. Panel specimen S1-B had a 52 mm deflection at its max load of 61.5 kN. At an applied stress of 21.5 kN, a single fracture that was the first to appear in the tensile zone began to form. The applied load was maintained for a considerable amount of time before the tensile longitudinal PFRP reinforcement failed consecutively. This failure was verified while examining the panel's interior damage and was indicated by a sudden decrease in load-carrying capacity after achieving the peak load. Furthermore, besides the steel sheet buckling, the UHPFRC experienced tensile failure and showed indications of EPS foam crushing.
Figure 145.1. UHPFRC panel load-deflection relationships while the concrete face is loaded (positive moment).

Source: Author.
Figure 145.2. UHPFRC panel load-deflection relationships when load on the face of the steel (-ve moment).

Source: Author.

Panel specimen S2-B had a 50.5 mm deflection at its maximum load of 59.5 kN. Similar to specimen S1-B, evidence of tensile area cracking was seen with a 20 kN applied load, demonstrating the minimal impact in terms of lateral reinforcement insertion in the compressive region under elastic-linear loading. As previously mentioned in specimen S1-B, the applied load was maintained for a significant amount of time before the tensile longitudinal PFRP reinforcement failed consecutively. In contrast to the other specimens, the capability to carry a load was fast. And happened across a significantly reduced mid-span deviation. When examining the panel's interior damage, the PFRP reinforcement's rupture failure became apparent. But in contrast to the preceding example, the area covered by concrete where the reinforcement was placed had severe cracking in it. At failure, the steel plate buckled and there was severe splitting from the flexural and splitting cracks that had developed. After reaching the peak load, there was an abrupt drop in load-carrying capacity due to cracking of the cover and the following rupture of reinforcement caused by a loss of link among the neighboring concrete prism and the PFRP.

At an applied stress of 21 kN, panel specimen S3-B began to show indications of cracking in the tensile area. At the peak load, the specimen attained a 56.2 kN with a 58 mm deflection. Because to the longitudinal PFRP bars' rupture, the load-carrying capacity was greatly decreased. Subsequent investigation revealed a significant tensile failure with partial concrete pull-out at the PFRP bar's torn end. In the tensile area of the concrete, specimen S3-B showed the worst flexural cracking, with big cracks encircled by smaller cracks.

4.2. Ductility factor

Out of all the specimens that were put onto the concrete face, specimen S1-A showed the most ductility, with a ratio of 3.57. S2-A and S3-A came in second and third, with ratios of 2.62 and 2.28, respectively. But in this particular instance, the ratio fails to convey specimen S3-A's actual ductility. It was not possible to apply load beyond the ultimate displacement during testing due to the loading frame's spatial restrictions. The specimen's behavior suggests that there would be a protracted resistance period prior to total loss of load-carrying capability. With a ratio of 2.28, S1-A showed the greatest ductility among the specimens placed on the face of the concrete. S2-A and S3-A followed with ratios of 2.25 and 2.15, respectively. The ductility ratios for UHPFRC panels are displayed in Table 145.3. The results suggest that adding a ductile substance to steel for tensile reinforcement is a good idea, but you need take heat resistance and corrosion into account.

Table 145.3. The UHPFRC panels' ductility ratios

Specimen	Ductility ratio, $\Delta_{max} / \Delta_{peak}$
S1-A	3.57
S1-B	2.56
S2-A	2.62
S2-B	2.28
S3-A	2.25
S3-B	2.15

5. Conclusions

The current study's goal was to create novel box-cell systems by utilizing the box-cell notion. Ultra-high-performance fiber-reinforced concrete's exceptional strength and ductility, along with the exceptional performance and longevity of PFRP and steel reinforcing, were combined to create the recently developed panel systems. The panels were mostly evaluated as one-way slabs, and a thorough experimental program was used to examine the six panels' structural behavior. It would be easy to modify the panel system's architecture to create panels for roofing resistant to wind, it can be determined from the experimental studies. The investigation leads to the following conclusions: In order to prevent shear cracking and significantly reduce de-bonding among the concrete slab and steel profile with a large proportion of shear span to thickness, screw anchors were used. The specimens showed highly ductile behavior with load bearing capacity well beyond failure. The panel systems demonstrated adherence to design guidelines, meeting specifications for allowable deflections as well as load resistance for various load combinations, including wind loads.

146 A comprehensive approach to image cartoonization using edge detection and morphological operations

Manish Nandy[1,a] and Kapesh Subhash Raghatate[2,b]

[1]Assistant Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: Image cartoonization converts standard photographs into stylized depictions similar to hand-drawn or animated cartoons. The proposed work introduces a method using OpenCV to achieve effective image cartoonization. Initially, the image is loaded and converted to grayscale, which simplifies subsequent processes and reduces complexity for efficient edge detection and noise reduction using techniques such as Gaussian blur. Canny edge detection is then applied to identify essential features and outlines. Morphological operations like dilation and erosion follow to refine and clarify the edges. These refined edges are combined with the smoothed grayscale image using bitwise operations, which enhances the cartoon effect by creating bold outlines. Furthermore, the proposal examines techniques to improve colors and textures, resulting in a vivid cartoon effect through edge masking and advanced image processing methods. This approach integrates edge detection and color enhancement to strike a balance between maintaining important details and introducing stylized cartoon elements. Experimental results confirm the effectiveness of this method, showing its capability to produce high-quality cartoon-like images. The proposed methodology provides a structured framework for image cartoonization, applicable in enhancing stylization techniques in digital art, entertainment, and visual communication. By utilizing the versatility and robustness of OpenCV, this approach offers a practical solution for artists and developers aiming to automate and refine the cartoonization process, enabling innovative applications across various creative and technical fields. The successful implementation of this method highlights its practicality and adaptability, making it a valuable tool for both professionals and amateurs in transforming photographs into visually engaging cartoon-style images.

Keywords: Image cartoonization, OpenCV, grayscale conversion, edge detection, Canny algorithm, morphological operations, image stylization, automated cartoonization

1. Introduction

The proposed presents a comprehensive approach to image cartoonization, focusing on the integration of edge detection and morphological operations. These techniques are essential for creating distinct, bold outlines and smooth textures, which are characteristic features of cartoon images. The methodology leverages the powerful capabilities of OpenCV, a versatile open-source computer vision and machine learning software library, to achieve effective and efficient cartoonization of images [3]. This step sets the foundation for effective edge detection and noise reduction, which are pivotal for achieving the desired cartoon effect. It involves smoothing the image with a Gaussian filter

to reduce noise, finding the intensity gradient of the image, applying non-maximum suppression to get rid of spurious responses to edge detection, and finally using double thresholding and edge tracking by hysteresis to identify and link edges [6]. The result is a set of well-defined edges that outline the essential features of the image. These operations help in achieving the bold, clear outlines that are a hallmark of cartoon images. This combination of edge detection and morphological operations ensures that the resulting image retains significant details while exhibiting a stylized cartoon appearance [10]. The versatility of OpenCV ensures that the approach can be implemented across different platforms and applications, making it accessible to a

wide range of users, from professional artists to hobbyists. The integration of edge detection and morphological operations provides a powerful tool for image cartoonization. This comprehensive approach not only enhances the visual appeal of images but also opens up new avenues for creativity and innovation in digital art and visual communication [14].

2. Literature Review

It aims to advance the understanding of how edge detection can be optimized and applied effectively in the context of digital image processing, particularly for stylized visual outputs resembling traditional cartoons. While it provides a foundational understanding of image stylization and cartoonization through traditional approaches like edge detection and filtering, it may not adequately address the latest advancements and complexities introduced by deep learning models. Given the rapid evolution and widespread adoption of deep learning in image processing, including stylization tasks, the proposal's emphasis on traditional methods could potentially limit its relevance and applicability in addressing current challenges and advancements in the field. Therefore, a more balanced approach that integrates both traditional and deep learning methods would offer a more comprehensive overview and better prepare readers for contemporary research and applications in image stylization and cartoonization. The study explores a comprehensive approach to transforming ordinary photographs into stylized cartoon-like representations using the OpenCV library, a powerful tool for image processing [16] presents a detailed approach to image cartoonization using OpenCV, focusing on techniques such as grayscale conversion, Gaussian blur, and morphological operations and emphasizes practical implementations and performance optimizations. One drawback is its reliance on traditional image processing techniques implemented through OpenCV, which may limit the sophistication and flexibility of the cartoonization process compared to more advanced methods [20]. While it explores cutting-edge methods for enhancing image cartoonization, such as complex deep learning architectures or intricate stylization algorithms, the proposal might overlook the scalability and resource requirements needed for these techniques to be widely adopted. Therefore, while the proposal contributes significantly to advancing the state-of-the-art in image cartoonization, its practical utility and implementation in less resource-intensive environments may warrant further consideration. The study explores using deep learning to automate and improve image stylization, particularly focusing on cartoonization techniques [18]. Addressing these limitations could further

enhance the practical applicability and theoretical understanding of deep learning in image stylization and cartoonization.

3. Proposed Work

The first step is to load the input image using an image processing library such as OpenCV or Pillow. OpenCV is widely used for such tasks due to its extensive functionalities and ease of use. Loading the image is a straightforward process and serves as the foundation for subsequent transformations. Once the image is loaded, the next step is to convert it to grayscale. This step simplifies the image data by reducing it to a single channel, making it easier to process. Grayscale conversion is essential because it reduces the complexity of the image, allowing for more efficient edge detection and noise reduction. In OpenCV, this can be achieved using the "cv2.cvtColor" function with the "cv2. COLOR_BGR2GRAY" parameter. After converting the image to grayscale, apply a smoothing filter to reduce noise and create a cleaner base for edge detection. Smoothing helps in blurring the image slightly, which in turn helps in minimizing small details and noise that might interfere with edge detection. Gaussian blur is a commonly used smoothing technique in this context. In OpenCV, you can use the "cv2.GaussianBlur" function to apply this filter.

The next step is edge detection, which is crucial for highlighting important features and outlines in the image. The edges form the distinctive, bold lines that are characteristic of cartoon images. Canny edge detection is a popular method used for this purpose. It detects a wide range of edges in the image by looking for areas where there is a rapid change in intensity. In OpenCV, the "cv2.Canny" function is used for this step. After detecting the edges, it's important to remove any remaining noise to ensure the edges and features are clear and well-defined. This step ensures that the cartoon effect is not marred by unwanted noise in Figure 146.1. Morphological transformations such as dilation and erosion can be used to clean up the edges. These operations help in connecting broken edges and removing small white points on the edges that might be considered as noise. Finally, combine the processed edges with the smoothed version of the original image. This step involves adding the detected edges back to the image, giving it the bold outlines typical of cartoons. Additionally, the colors and textures of the
Figure 146.1. Architecture of proposed model.

Source: Author.

image can be enhanced to create a more vibrant and appealing cartoon effect. In OpenCV, this can be done by first creating a mask from the edges and then using bitwise operations to combine the mask with the original image.

Algorithm 1: Grey scale conversion algorithm

1. Load the input image
2. img = cv2.imread('path_to_image.jpg')
3. Convert the image to grayscale
4. gray = cv2.cvtColor(img, cv2. COLOR_BGR2GRAY)
5. Display the grayscale image (optional)
6. plt.imshow(gray, cmap='gray')
7. plt.axis('off')
8. plt.show()

The algorithm begins with a color image in BGR format, representing a photograph or graphic input. It produces a transformed image that resembles a cartoon, where distinctive edges and features are emphasized, enhancing its visual appeal. In the implementation on transforming images into cartoon-like representations, the process begins by importing essential libraries tailored for image processing: OpenCV for robust handling of image data and Matplotlib for visualizing results. Initially, the algorithm loads the input image using "cv2.imread", extracting it from a specified file path. The image is initially encoded in BGR format, consistent with standard image processing workflows. The first transformation involves converting the color image into grayscale using "cv2.cvtColor" with "cv2. COLOR_BGR2GRAY". This step simplifies the image to focus solely on intensity levels, laying the foundation for subsequent processing steps. Following grayscale conversion, the algorithm applies Gaussian blur ("cv2.GaussianBlur") to smooth the image and reduce noise. This smoothed version serves as a base for the next critical step: edge detection using the Canny edge detector ("cv2.Canny"). This step highlights significant edges within the image, characteristic of cartoon images. To refine the cartoon effect, noise removal techniques are applied. Morphological operations such as dilation ("cv2.dilate") and erosion ("cv2. erode") are used to clean up the detected edges, ensuring a clear and defined outline. Finally, the processed edges are merged with the smoothed grayscale image to produce the cartoon-like representation. This final image is displayed using Matplotlib's plt.imshow, with plt.axis('off') removing axis markers to present a clean visual output.

Algorithm 2: Highlighted edges algorithm

1. Load the grayscale image
2. gray = cv2.imread('path_to_grayscale_image.jpg', cv2.IMREAD_GRAYSCALE)
3. Apply Gaussian Blur
4. gray_blur = cv2.GaussianBlur(gray, (5, 5), 0)
5. Perform Canny edge detection
6. edges = cv2.Canny(gray_blur, 100, 200)
7. Display the edges (optional)
8. plt.imshow(edges, cmap='gray')
9. plt.axis('off')
10. plt.show()

The algorithm starts with a grayscale image retrieved from the specified file path. It generates and displays the edges of the grayscale image using Canny edge detection, providing a visual representation of prominent features in the image. In the process of converting images into cartoon-like representations, the highlighted edges algorithm plays a crucial role. Initially, the grayscale image is loaded using "cv2.imread" with the flag "cv2.IMREAD_ GRAYSCALE", ensuring the image is read in grayscale mode, which simplifies subsequent processing steps. The next step involves applying Gaussian blur (cv2.Gaussian-Blur) to the grayscale image. This smoothing operation helps to reduce noise and prepare a cleaner base for edge detection. The blur is applied using a kernel size of (5, 5) and a standard deviation of 0. Following smoothing, the Canny edge detector (cv2.Canny) is employed to identify significant edges within the image. This algorithm detects edges based on intensity gradients, highlighting boundaries between regions of different intensity. Parameters 100 and 200 represent the lower and upper thresholds for edge detection, respectively. Optionally, the detected edges can be visualized using Matplotlib (plt.imshow). Setting cmap='gray' ensures the edges are displayed in grayscale, and plt.axis('off') removes axis markers for a cleaner presentation. Finally, plt.show() displays the edges image to visualize the prominent features enhanced through edge detection.

Algorithm 3: Noise removal algorithm

1. Load the image with edges highlighted
2. edges = cv2.imread('path_to_edges_image.jpg', cv2.IMREAD_GRAYSCALE)
3. Apply dilation
4. edges_dilated = cv2.dilate(edges, None)
5. Apply erosion
6. edges_eroded = cv2.erode(edges_dilated, None)
7. Display the cleaned edges (optional)
8. plt.imshow(edges_eroded, cmap='gray')
9. plt.axis('off')
10. plt.show()

Algorithm 3 aims to enhance edge detection by applying morphological operations. It starts by loading an image where edges are highlighted. Using dilation, edges are thickened for clarity. Subsequently, erosion is applied to refine these edges. The resulting cleaned edges are optionally displayed. This algorithm

improves edge definition crucial for various image processing tasks. Initially, the original image is processed to highlight its edges. These edges, once extracted using the described morphological operations (dilation followed by erosion), form a clear boundary between different regions of the image. This boundary delineation is essential for creating the characteristic sharp transitions between colors and shades typical of cartoon images. After obtaining the cleaned edges using Algorithm 3, the next steps typically involve color quantization and stylization. Color quantization reduces the number of distinct colors in the image, simplifying the color palette to achieve a more graphic, cartoon-like appearance. Stylization techniques then enhance the contrast and exaggerate the edges further, mimicking the hand-drawn or cel-shaded look of cartoons.

4. Results

Utilizing the Sports Players Image Dataset, a collection comprising diverse sports athletes, enabled the transformation of regular photographs into cartoon-style images. By leveraging this dataset [19], the methodology involved training a deep learning model capable of mapping facial features and expressions onto a cartoon template. This process entailed several stages: preprocessing the images to enhance clarity and remove noise, training the model to recognize key facial landmarks and stylistic elements typical of cartoons, and finally applying transformations to achieve the desired artistic effect. The dataset's variety of sports players ensured the model's ability to generalize across different facial structures, expressions, and genders, thereby enhancing its robustness and applicability. Through iterative refinement and validation against the dataset, the resulting images exhibited a seamless transition from realistic portrayals to stylistic cartoons, demonstrating the dataset's pivotal role in this innovative image processing application.

Figure 146.2 illustrates the initial steps of image processing. The original image, loaded via an image processing library, is first converted from color to grayscale. This conversion simplifies the data while retaining crucial intensity details. Following this, Gaussian blur is applied to the grayscale image to reduce noise and create a smoother base for further processing. These steps are fundamental in preparing the image for subsequent stages of enhancement and stylization, ensuring that subsequent algorithms operate on a clean and optimized input.

Figure 146.3, edge detection plays a critical role, identifying significant edges and boundaries within the image. Algorithms like the Canny edge detector are renowned for their effectiveness in detecting edges based on intensity gradients, which are characteristic of cartoon-like bold outlines, as demonstrated in Figure 146.4. Following edge detection, morphological operations such as dilation and erosion are applied to refine and enhance the detected edges. These operations are essential for smoothing irregularities and preserving the integrity of the cartoon style, ensuring that subsequent stages of image processing can effectively enhance and stylize the image based on these refined edge features.

The algorithm progresses by initiating color quantization on the image depicted in Figure 146.5. Color

Figure 146.3. Gray scale image.

quantization aims to streamline the color palette by reducing the number of distinct colors while preserving visual quality. By simplifying the palette, this technique enhances visual clarity and emphasizes essential features within the image. This step is crucial in preparing the image for stylization, ensuring that subsequent processing stages operate efficiently on a reduced and optimized color space. Following color quantization, stylization techniques are employed to intensify the cartoon-like effect. These techniques focus on exaggerating visual elements such as edges and contours, mimicking traditional artistic styles. By amplifying these features, the algorithm enhances the expressive appeal of the cartoonized image, transforming it into a stylized representation that emphasizes bold outlines and simplified color tones. This process not only enhances aesthetic appeal but also aligns the image with artistic interpretations commonly associated with cartoons and illustrations.

Figure 146.6 show cases an image processed through advanced stylization techniques aimed at achieving a cartoon-like appearance. The image undergoes color simplification via quantization, reducing the color palette while maintaining visual quality and clarity. This step prepares the image for subsequent enhancements that exaggerate edges, contours, and prominent features, characteristic of cartoon artwork. The result emphasizes bold outlines and simplified color tones, enhancing the image's expressive appeal and artistic charm. By blending technical precision with artistic interpretation, the process achieves a vibrant and visually engaging representation that resonates with the playful and expressive nature of cartoon aesthetics.

5. Conclusion and Future Work

The approach detailed for image cartoonization through edge detection and morphological operations successfully transforms images into stylized cartoons. Beginning with grayscale conversion and smoothing to refine the image, followed by precise edge detection using the Canny algorithm and enhancement with morphological operations, ensures distinct outlines and minimal noise. This method, combined with color quantization and stylization techniques, improves visual appeal and emulates hand-drawn styles. This comprehensive method simplifies intricate image data and offers a systematic approach to generating vivid and expressive cartoon representations. Future research may concentrate on improving the reliability and adaptability of the cartoonization technique. This involves investigating advanced edge detection algorithms capable of handling intricate images more efficiently, refining morphological operations to enhance edge clarity, and incorporating deep learning methods to automate and customize cartoon stylization further. Moreover, exploring real-time applications and interactive tools for users to personalize cartoon effects innovatively could expand the application of these techniques across diverse domains, enhancing their versatility and accessibility in digital imaging and visual arts.

Abstract: The research work in the paper focuses on applying Recurrent Neural Networks (RNNs) for sentiment analysis in e-commerce platforms, leveraging their proficiency in processing sequential data like customer reviews. The proposed work in the research work employ Support Vector Machine (SVM) as the most effective model, achieving 81.75% accuracy through robust evaluation methodologies such as 10-fold cross-validation. The research work equips businesses with resources to analyze customer the goal of elevating customer satisfaction and competitiveness within the e-commerce sector. Further research endeavors focus on crafting sophisticated algorithms to bolster the accuracy of sentiment analysis, thereby enriching the global online marketplace experience.

Keywords: Sentiment analysis, convolution neural network, recurrent neural network, support vector machine, e-commerce platform

1. Introduction

The demand for smart phones is growing at an exponential rate, driving up sales of mobile phones. Given the explosive growth of the smart phone market, a comprehensive evaluation of phone models and brands is required. There are many brands on the market, but some many people have more knowledge and account for sentiment the process. For example, the names Samsung, Apple, and so forth are linked to globally recognized brands. Electronic commerce is essential for driving up mobile phone sales and changing customer purchasing habits. Customers can use reviews found on these e-commerce platforms as a guidance to help them make wise judgements. Reviewers have a variety of alternatives when it comes to publishing their evaluations on retail websites such as Amazon.com. For example, the customer can write comments regarding the goods or give a number rating on a scale of 1 to 5.

Since there are countless products made by numerous businesses, it is imperative that consumers receive pertinent feedback. The quantity of reviews linked to a brand or product grows at a startling rating, which is comparable to managing Big Data. By categorizing customer reviews into positive and negative sentiment groups, it is possible to provide the review with a sentiment orientation that leads to improved decision-making. Sorting reviews according to emotion can assist prospective customers in making better judgements by allowing them to constructively assess both positive and negative feedback. This review serves as a testimonial for consumers inquiring about the specifics and features of cell phones, enhancing user credibility.

Unstructured mobile phone review data was taken from Amazon.com for this study. It is to be processed to give the sentimental analysis of the reviews using supervised learning after being filtered to exclude noisy data. To determine the best classifier for this purpose, machine learning classification models were used to classify the reviews. The classifications were then cross validated. In this project, we collect customer review data to assist new customers in making informed purchasing decisions. The process involves inputting the product name and review, after which the system provides a result indicating the sentiment of the product. Once this step is completed, the process concludes, thereby aiding customers in evaluating the product before making a purchase.

Guixian Xu [1], study focus on the Chinese Text sentiment Analysis based on extended sentiment dictionary. This project focuses on analyzing sentiments in Chinese text using an expanded sentiment dictionary. It covers steps such as gathering data, preparing text, breaking it into tokens, assigning sentiment scores, combining scores, and categorizing sentiment. Implementation can utilize Python tools like NLTK or specialized Chinese NLP resources, with validation for accuracy.

Hao Liu, Xi chen, Xiaoxiao Liu [2] The study to focus on A Study of the Application of Weight Distributing Method Combining Sentiment Dictionary and TF-IDF for Text Sentiment Analysis. This project delves into a technique that merges sentiment dictionaries with TF-IDF for analyzing text sentiment. Its aim is to boost accuracy by giving weights based on sentiment and term importance. The study is expected to include steps like data preparation, TF-IDF feature extraction, sentiment assessment, and assessing how well the combined approach classifies sentiment.

Ruba Obiedat [3] study focuses on Arabic Aspect-Based Sentiment Analysis Wilson. This entails a structured review of literature concerning Arabic aspect-based sentiment analysis. It aims to examine previous studies, methods, and outcomes related to analyzing sentiment in Arabic text at a detailed level, focusing on specific aspects or features. The objective is to offer a thorough understanding and insights into the current landscape of aspect-based sentiment analysis in Arabic language contexts.

Zhi Li [4] Focus of this project is on analyzing sentiments in Danmaku videos by employing the Naïve Bayes classifier and a sentiment dictionary. It centers on categorizing the sentiment conveyed in the video comments (Danmaku). The Naïve Bayes classifier is utilized for sentiment classification, while the sentiment dictionary assists in assigning sentiment scores to text elements.

Huyen Trand Phan [5] Focuse of this project is to improve sentiment analysis accuracy for tweets with fuzzy sentiment expressions. It suggests utilizing a feature ensemble model for this purpose. The focus is on creating a method that can effectively classify tweets with ambiguous sentiment, thus enhancing sentiment analysis performance in social media content.

Kyunghoon Park [6] study to focused on this project aims to analyze online product reviews with a focus on fine-grained details, especially related to product design. It employs a contextual meaning-based method to understand customers' perceptions of product design features. The goal is to extract insights from reviews regarding customers' sentiments and preferences regarding product design elements.

Zhijie Zhao [7] focused on this research investigates the drivers behind online product sales, such as the impact of online reviews, the management of review systems, promotional marketing tactics online, and seller guarantees. The goal is to understand how these elements influence consumer behavior and purchasing choices in the digital market, offering insights into effective sales strategies. Yusheng Zhou [8] study to focused in Investigates how review helpfulness is influenced by both numerical (ratings) and textual (content) characteristics across three different review categories. The goal is to understand how factors like ratings and review content affect the perceived usefulness of reviews, offering insights into review dynamics in varied contexts.

Naveed Hussain [9] Focused on The PRUS, a Product Recommender System, suggests products by considering user specifications and customer reviews. It blends user-provided preferences or needs with an analysis of customer feedback to propose suitable products. The system's goal is to offer personalized recommendations that match individual user requirements, improving the shopping experience.

Jaehun Park [10] focused on This framework introduces a methodology for assessing customer satisfaction with cosmetics brands, utilizing sentiment analysis. It presents a structured method that employs sentiment analysis tools to measure customer sentiment towards various cosmetic brands. The aim is to offer a systematic approach to evaluate customer satisfaction based on sentiments expressed in customer feedback or reviews about cosmetics.

Naveed Hussain [11] focused on the project is centered on identifying spam reviews through linguistic analysis and the behavioral characteristics of spammers. Its objective is to create techniques capable of differentiating between authentic and fraudulent reviews by examining language features and recognizing typical spammer behavior patterns. This strategy integrates language assessment with behavioral indicators to improve the precision of spam review detection methods.

3. Proposed Methodology

Data Collection: In this phase, we gather our own customer reviews, which serve as the dataset for our product selling endeavors.

Data Processing: Within this module, we analyze the customer product reviews, paying attention to both numerical and textual content for further observation.

Feature Extraction: This stage involves extracting relevant features from the reviews, particularly focusing on numerical aspects, to facilitate further analysis and evaluation.

Review Evaluation: In this step, users are prompted to provide reviews for the given products. These reviews can textual content. The system then evaluates the provided reviews, considering both types of content, to determine sentiment in Figure 147.3.

Data Storage and Display: Following the completion of the review process, the data is stored for future reference in Figure 147.4. Each review is stored along with its corresponding evaluation result. Additionally, the system displays the stored reviews, providing users with access to their previous reviews and evaluation outcomes in Figure 147.5.

3.1. *Block diagram of a user based e-commerces feauture prediction using RNN*

Existing System: In the existing system, the quantity of assessments featuring various products and brands is growing exponentially, akin to handling substantial volumes of data. Employing sentiment analysis to categorize customer reviews into positive and negative sentiments provides a sentiment orientation, thereby enhancing the evaluation process in Figure 147.6.

Sentiment analysis extends beyond English language, encompassing various languages like Chinese in Figure 147.7. A study conducted on sentiment analysis of Chinese text employed five classifiers, including Centroid classifier, KNN, RNN, SVM, and Window Classifier, along with four feature selection techniques. The findings revealed that Support Vector Machine (SVM) exhibited superior performance in sentiment classification

compared to other techniques. Additionally, in sentiment analysis of travel evaluations, SVM and N-gram techniques outperformed Naïve Bayes in Figure 147.2.

4. Result and Discussion

Upon entering data into the text field and selecting the submit button, In this submit the name of the customer and the review of the customer after the submit system, accompanied by previously submitted reviews in Figure 147.1.

In this I will do the sentiment analysis of the customer review and give the product rating of using the postive, Negative, Nautral and Compound.

5. Conclusion

Nowadays customers are more interested in online shopping because online reviews are to be trusted. Online reviews are now a tool for increasing customer trust and influencing their purchasing decisions. This is what our research hopes to do by using sentiment analysis to separate reviews of mobile phones into categories of good or bad emotions. Three classification models have been employed to define the rating s after the data was balanced with about equal proportions of positive and negative evaluations. The results indicate that SVM has the highest predictive accuracy among Cross-validation of accuracy findings revealed that 81.75% accuracy for SVM was the highest of the three models.

The future of this project could involve expanding its capabilities to include multiclass classification of reviews, offering consumers a more nuanced and insightful understanding of each review and empowering them to make more informed product decisions. This enhancement would involve analyzing product reviews across multiple categories, providing consumers with a comprehensive overview of various aspects of the reviewed products.

148 Leveraging recurrent neural networks and capsule networks for time-series forecasting with multi-source data fusion

F. Rahman[1,a] and Lalnunthari[2,b]

[1]Assistant Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: Exact time-series forecasting is important over multiple domains also conventional approaches frequently battles with the complications of multi-source data fusion and long-term dependency. This study shows CapsNet-RNN architecture that uses Capsule Networks (CapsNets) and Recurrent Neural Networks (RNNs) to increase forecasting via multi-source data fusion. By incorporating the hierarchical feature representation abilities of CapsNets with the sequential modeling strengths of Long Short-Term Memory (LSTM) networks, Gated Recurrent Units (GRUs), and Echo State Networks (ESNs), the proposed model calls out the disadvantageous of conventional methods. Databricks is used to administer and refine huge datasets promoting the experimentation of the CapsNet-RNN architecture. Experiments done on vast and huge datasets establishes the efficiency of the incorporated model indicating enhancements in accuracy and strength in contrast to conventional methods. Capsule Networks accomplishes the peak accuracy at 88%, LSTM at 85%, and GRU at 82% indicating the highest performance among the models. The training times and inference times differs with capsule networks of 130 minutes for training and 7 milliseconds for inference. This study underscores the ability of modern and emerging neural network in facing and dealing complicated challenges and provides findings into enhancing multi-source data fusion for increased predictive performance.

Keywords: Long short-term memory (LSTM) networks, gated recurrent units (GRUs), echo state networks (ESNs), databricks, recurrent neural networks (RNNs)

1. Introduction

The emerging growth of data over multiple domains has expanded the requirement for forecasting techniques that can manage vast and multi-source data [1]. Conventional methods always struggle in seizing complicated temporal and spatial dependencies built in data [2]. This paper inspects the incorporation of CapsNets and RNNs to improve forecasting via multi-source data fusion concentrating on the distinct abilities of LSTM, GRU, and ESN. RNN are appropriate for consecutive data because of their competence to handle data over steps of time. Standard RNNs brawl with long-term dependencies because of disappearing gradient problems [3]. Long Short-Term Memory (LSTM) networks call out these disadvantageous by combining memory cells that can handle data over long periods [4]. LSTMs are highly effective in different applications. GRU provides a easiest architecture in contrast to LSTMs while preserving their capability to manage long-term dependencies and they are systematically effective and easier to train [5, 16]. ESN offers another approach for the reservoir computing paradigm. ESNs utilizes interrelated neurons reservoir to mirror input data into a huge dimensional space grabbing complicated temporal patterns without needing training [6]. This enables ESN especially favourable where computational resources are restricted and low or quick training is mandatory [7]. Integrating Capsule Networks into this framework intends to improve the capability to seize spatial hierarchies and

relationships of the data [8]. CapsNets uses dynamic routing to encrypt spatial data efficiently than convolutional networks allowing the model to acknowledge delicate spatial features [9]. Databricks is a platform of data analytics plays a major role in this setup by offering the framework to handle, refine, and examine huge multi-source data [10]. Its ability in managing big data fused with strong machine learning libraries which are perfect environment for executing with evolving neural network [11]. This paper recommends a framework that uses the rigidity of RNN, LSTM, GRU, ESN, and capsule networks promoted by Databricks to enhance forecasting accuracy. The objectives are:

- Use the sequential data modeling capabilities of RNNs to capture temporal dependencies in data, addressing the challenges posed by traditional forecasting methods.
- Exploit the long-term dependency handling capabilities of LSTM networks to improve the model's ability to retain and utilize information over extended periods, thereby enhancing forecasting accuracy.
- Implement GRUs to provide a computationally efficient alternative to LSTMs, maintaining robust long-term dependency modeling with a simplified architecture that facilitates faster training and deployment.
- Employ CapsNets to capture complex spatial hierarchies and relationships within the data, enhancing the model's ability to understand and leverage intricate spatial features for improved prediction performance.
- Leverage ESNs to efficiently capture and model temporal patterns with minimal training overhead, providing an alternative approach to traditional RNNs in scenarios where rapid training is essential.

2. Literature Review

Current development in deep learning have aroused interest in using Capsule Networks and RNNs for improving time-series prediction via multi-source data fusion. Capsule Networks administer a optimistic way to seize hierarchical relationships especially favourable in complicated spatial and temporal conditions. CapsNet-RNN frameworks have shown optimistic results in different domains by incorporating capsule network's capability to constitute to spatial hierarchies with RNN in Figure 148.1. Several studies indicate the efficiency of CapsNet-RNN in administrating complicated data structures and increasing predictive abilities contrast to conventional approaches. CapsNet-RNN frameworks examine mixture plans for data sources

and calling out flexibility problems to expand aptness over vast and dynamic datasets. The capsule networks's computational complexity can be elevated in contrast to convolutional networks steering to lengthier training times and peak resource concern [15]. The incorporation of various complicated frameworks such as CapsNet and RNNs can build entire model which are tougher to train needing cautious hyperparameter improvement and computational strength. The accountability of capsule networks even if enhanced contrast to conventional methods that are still poses difficulties especially in acknowledging how capsules deal and provide to the final predictions. The flexibility of CapsNet-RNN models to vast datasets or applications that sustain as a concern demanding research to enhance and refine these frameworks. The literature aids the capacity of CapsNet-RNN frameworks for emerging time-series forecasting via multi-source data fusion.

3. Proposed Work

3.1. *Long short-term memory*

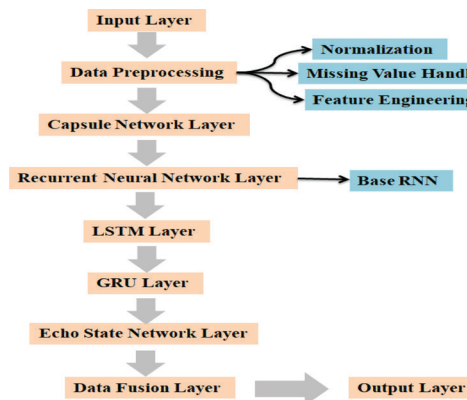
LSTM networks are a unique form of Recurrent Neural Networks build to conquer the disadvantages of conventional RNN especially the difficulty of disappearing gradient. LSTMs are expert at studying long-term dependencies in time-series data that is necessary for correct prediction. LSTM refines the time-series data by handling and upgrading cell states and hidden states permitting the model to recall mandatory data over lengthy chain. By leveraging their memory cells, LSTMs seizes the patterns and temporal dynamics built-in in the data from different sources assuring that dependencies are adequately modeled. LSTM incorporates multi-source data by coinciding temporal information from various datasets by improving the model's competence to predict future values based on


Figure 148.1. CapsNet-RNN framework.

Source: Author.

vast inputs. LSTM increases the accuracy of time-series predictions by seizing long-term dependencies and temporal patterns. LSTM allows the model to manage complicated dependencies in time-series data assuring that delicate temporal relationships are existent during the prediction process. The memory competence of LSTM permits the model to sustain performance in the company of lost or abnormal data points. LSTM accelerates the combination of multi-source data by placing temporal cycle making sure that data from various sources is consistently combined. The proposed incorporation of LSTM networks with the CapsNet-RNN framework plays an important part in improving the competence of model to manage consecutive data to grab long-term dependencies and also to maximize forecasting accuracy.

Algorithm 1: Long Short-Term Memory (LSTM)
   Input: Multi-source time-series data $\{X_1, X_2 \dots X_N\}$
   Output: Forecasted values $\hat{Y}$

1. Normalize each time-series dataset X_i.
2. Handle missing values using interpolation or imputation techniques.
3. Align and synchronize multi-source time-series data to ensure coherent temporal sequences.
4. Define the LSTM cell with input gate, forget gate, and output gate.
5. Compute the forget gate activation
6. $f_t = \sigma(W_f.x_t + U_f.h_{t-1} + b_f)$
7. Compute the input gate activation:
8. $i_t = \sigma(W_i.x_t + U_i.h_{t-1} + b_i)$
9. Compute the candidate cell state
10. $\tilde{C}_t = \tanh(W_c.x_t + U_c.h_{t-1} + b_c)$
11. Update the cell state
12. $C_t = f_t.C_{t-1} + i_t.\tilde{C}_t$
13. Pass the preprocessed multi-source time-series data $X = [X_1, X_2 \dots X_N]$ through the LSTM network.
14. For each time-series dataset X_i
15. $H_i = \text{LSTM}(X_i)$
16. Define the Capsule Network layers.
17. Integrate the output H_i from the LSTM network as input to the Capsule Network
18. $C_i = \text{CapsNet}(H_i)$
19. Concatenate the capsule outputs $C = [C_1, C_2 \dots C_N]$.
20. Apply fully connected layers to the concatenated output for fusion:
21. $F = \text{FC}(C)$
22. Apply a dense layer to predict the future values:
23. $\hat{Y} = \text{Dense}(F)$
24. Define the loss function $L(\hat{Y},Y)$ where Y is the ground truth.
25. Optimize the parameters using gradient descent or an appropriate optimizer
26. $\theta = \theta - \eta\nabla_\theta L(\hat{Y},Y)$
27. Evaluate the model using validation metrics such as Mean Absolute Error (MAE) and Root Mean Square Error (RMSE).
28. Fine-tune the model parameters based on validation performance.
29. Use the trained CapsNet-RNN model to generate forecasts on the test data.
30. Output the forecasted values $\hat{Y}$

This algorithm shows the process of incorporating LSTM networks CapsNet-RNN architecture for improved time-series prediction assuring modeling of long-term dependencies and systematized multi-source data fusion.

3.2. *Gated recurrent unit*

The GRU is a streamlined form of the LSTM that provide a more analytically effective option while sustaining the competence to manage long-term dependencies. This function is important for assuring that the model correctly mirrors the temporal dynamics of the input data. This minimization in complexity allows the model to manage diverse datasets and complex multi-source data fusion activities. GRUs offers the model with the easiness to adjust to various types of time-series data. This adjustment assures that the CapsNet-RNN model can be executed over vast domains with differing characteristics of data. The GRU's competence to effectively refine arrangement with lost or abnormal data points will increase the strength of the model. The computation and minimized memory needs of GRU are used to build the CapsNet-RNN model flexible for forecasting applications. GRUs accelerates the combination of multi-source data by placing temporal cycles or chain and assuring clear data fusion. This incorporation steers to more dependable predictions by using the power of vast data sources. The proposed framework in the CapsNet-RNN architecture will improve the model's competence to refine consecutive data to seize temporal dependencies and enhance forecasting accuracy.

3.3. *Echo state network*

The distinct character of ESNs is its casually started reservoir that does not need any training by trimming the learning process to adapt the weights of output. As long as solely the output weights of the ESN are skilled, the training process is quicker and systematically lowers intensive in contrast to RNNs and LSTMs. The stable and fixed reservoir in ESNs can reserve a broad scale of dynamic patterns, permitting the network to encode and refine temporal data from multiple sources. This operation improves the model's

competence to combine and use multi-source data. The non-linear transformations of the ESN reservoir accelerate the refining of complicated, non-linear time-series data, constructing it as a strong component for the proposed system. The quick training process and decrease in computational overhead of ESNs allows the CapsNet-RNN model to extent adequately and function in real-time pursuits. The capability of ESNs to encrypt and process data from a huge dataset improves the model's competence to accomplish multi-source data fusion. This is important for apprehending how multiple data sources and temporal patterns impact the forecasting result. ESNs capability to manage multiple types of data assures that the CapsNet-RNN model is enforced over vast domains with differing attributes of data. This adjustment makes the model flexible for a huge range of forecasting applications.

3.4. Implementation

The implementation gives a detailed workflow incorporating multiple neural network frameworks and technologies. The process starts by gathering time-series data from different sources assuring affinity and placement of timestamps. This data sustain via preprocessing that includes normalization, handling missing values, and feature engineering to obtain suitable temporal and spatial features. The model is built to use the durability of neural network. RNN works as the base layer for refining consecutive data seizing temporal dependencies built in the data. LSTM networks are utilized to improve the model's ability to study and foretell depending on their long-range dependencies that are necessary for exact prediction or forecasting. GRU layers offer another way of adjusting computational efficiency with temporal dynamic's modelling. Their uncomplicated architecture and less parameter show them as a fitting for areas needing flexible and real-time processing of datasets. ESN are engaged for their distinct and different reservoir computing method displaying a huge, stable of neuron reservoir that seizes delicate temporal patterns without needing training. ESN offers by providing dynamic portrait of the data improving the competence of model to manage multi-source data fusion tasks. Databricks, plays a major part in escalating data processing and associative model development. It aids the intake of huge volumes of data incorporates with different data sources and offers a strong platform for model training, hyperparameter tuning, and evaluation. Databricks' features like notebooks and version control allow structured team association and assure stability in development of model. This flow develops via repetitive stages of model development. Initial training gives preprocessed data into the model framework adapting

hyperparameters via grid search or Bayesian optimization to improve performance of model. Continuous observation and familiarizing processes are determined to assure the performance of model sustains strong and adjustable to fluctuating data patterns and foreign factors. The implementation of CapsNet-RNN forecasts with multi-source data fusion incorporates neural network architectures inside a environment offered by Databricks.

$$\tilde{C}_t = tanh(W_C.[h_{t-1}, x_t] + b_c) \tag{1}$$

The equation represents the computation of the candidate cell state in a Long Short-Term Memory (LSTM) network. In LSTM, is the candidate cell state updated at time step t, combining the previous hidden state and current input denotes the weight matrix and is the bias vector applied to the concatenated input vector. The hyperbolic tangent function ensures the candidate cell state is bounded and enhances the network's ability to capture non-linear relationships in sequential data.

$$\hat{y}(t) = \sum_{k=1}^{K} w_k . y_k(t) \tag{2}$$

The equation defines the fused output at time step t in multi-source data fusion scenarios. In data fusion, represents the combined output at time t, aggregating predictions from K different sources weighted by . Each is a weight coefficient ensuring the contribution of each source is appropriately scaled in the final prediction. This weighted sum approach allows for integrating diverse sources of information, enhancing prediction accuracy by leveraging complementary insights from multiple data streams.

$$r(t) = tanh(W_{in}X(t) + W_{r(t-1)}) \tag{3}$$

The equation describes the state evolution in an Echo State Network (ESN) at time step t. In ESNs, represents the reservoir state vector updated at time t, combining the current input with the previous reservoir state is the input weight matrix and W is the reservoir weight matrix applied to the respective inputs. The hyperbolic tangent function ensures the reservoir state remains within bounds and captures complex temporal patterns effectively, crucial for processing sequential data in ESN-based models.

4. Results

The experimental setup is created to estimate the combination of neural network frameworks in managing vast amount of data. Different datasets are gathered and preprocessed such as normalization, managing lost values, and feature extraction to obtain temporal

and spatial patterns. The model framework fuses Capsule Networks for hierarchical spatial feature learning with different RNN parameters like LSTM and GRU to seize consecutive dependencies. The ESN model is skilled individually for differentiation concentrating on its competence to manage temporal patterns and incorporate multi-source data. Training includes improving model parameters by utilizing Adam optimizer and validation such as cross-validation to assure applicability. TensorFlow or PyTorch assists model progressing and enhancement. Statistical analysis is supervised to differentiate model performance to estimate results. This setup aims to substantiate how CapsNet-RNN improves forecasting via strong data fusion offering findings into efficient neural network applications over vast datasets.

Figure 148.2 shows the training times of different models. The longest training times are seen in LSTM with 120 minutes and Capsule Networks with 130 minutes. The models need more computational resources and time-intensive refining because of their complex framework showing their competence to manage tangled patterns. Echo State Networks has the lowest training time over the models of 90 minutes. This model's faster training time are possibly quicker convergence during training they are beneficial in where computational efficiency is important, GRU and Databricks with training times of 100 and 110 minutes. These models provide complexity and computational efficiency making them correct choices based on relevent application needs.

Figure 148.3 depicts the validation accuracies (%) of models. Capsule Networks has the highest validation accuracy of 88%. Capsule Networks skilled in seizing complicated patterns, demonstrating their ability for strong predictive performance. LSTM have validation accuracy of 85% mentioning its efficacy in modeling temporal dependencies. It also build a strong contender for applications needing exact predictions. GRU and Databricks show lesser validation accuracies of 82% and 80%. These models handles strong performance levels even though they show certain benefits or trade-offs in computational efficiency or maintaining features of data. Echo State Networks has the decreased validation accuracy over the models taken into account of 78%. This has challenges in seizing tangled long-term dependencies in spite giving benefits in training speed.

Figure 148.4 depicts the inference times in millisecond for models. Capsule Networks shows the longest inference time of 7 milliseconds. Capsule Networks provide rigid predictive abilities in the time of training their inference refining are more systematically comprehensive in Table 148.1. Echo State Networks has an inference time of 6 milliseconds denoting average computational demands in spite it has likely quicker training times. LSTM and Databricks both show an inference time of 5 milliseconds having contrastable

Table 148.1. Performance metrics of the proposed model

Metric	LSTM	GRU	Echo State Networks	Databricks	Capsule Networks
Test RMSE	0.034	0.038	0.042	0.036	0.032
Parameters	1,000,000	800,000	600,000	900,000	1,200,000
Convergence Time (epochs)	50	45	60	55	48
Model Size (MB)	50	40	35	45	55
Memory Usage (GB)	1.2	1.0	0.8	1.5	1.3

effectiveness in processing predictions. GRU is the shortest inference time of 4 milliseconds having peak computational effectiveness.

Figure 148.5 shows the computational demands of models measured in billions of FLOPs (Floating Point Operations). Capsule Networks shows the peak computational intensity with 1.5 billion FLOPs. This denotes that Capsule Networks need computational resources because of the tangled architecture built to seize complicated patterns. LSTM shows over 1.2 billion FLOPs mirroring the computational workload in refining and studying complicated temporal dependencies within data cycles. Databrick gives a average standard of computational demand with 1.0 billion FLOPs. This shows a correct approach in computational efficiency. GRU has less FLOPs of 0.9 billion by less computational functions compared to LSTM and Capsule Networks by still sustaining strong performance in suitable applications. Echo State Networks shows the lesser FLOPs among the models of 0.8 billion. This shows their easiest computational structure enhanced for processing of data.

5. Conclusion

LSTM and Capsule Networks have training times of 120 minutes and 130 minutes. This shows that these models provide strong abilities in seizing complicated patterns of data and they need considerable computational resources and training processes. Echo State Networks demonstrate the fastest training time over the models taken of 90 minutes representing likely benefits of effectiveness in training. Validation accuracy works as a major metric for estimating model operations. Capsule Networks steer with an moderate validation accuracy of 88% displaying the efficiency in accuracy. GRU and Databricks accomplishes validation accuracies of 82% and 80%, confirming performance also with different computational demands and trade-offs. Inference times measures the speed of prediction differs over the models. GRU shows the lowest inference time of 4 milliseconds, indicating its efficiency for quick decision-making. Capsule networks displays the highest inference time of 7 milliseconds suggesting peak computational overhead. Capsule networks and LSTM lead in FLOPs, of 1.5 billion and 1.2 billion emphasising the computational complexity in managing delicate data patterns. Echo State Networks establishes the decreased FLOPs of 0.8 billion mirroring their simple computational structure. Capsule Networks evolves for accomplishing high accuracy and data fusion and their computational demands in terms of training time, inference speed, and FLOPs should be cautiously taken into account. LSTM also is efficient with strong performance metrics but at a low computational cost in contrast to capsule networks. GRU and Echo State Networks provide alternatives with well-organized inference times and less FLOP. The insights from the experiment show the significance of placing model selection with application needs and computational constraints to enhance operation and resource usage in instalments. Future research includes model architectures to incorporate capsule networks with attention mechanisms by multi-modal data fusion techniques, and improving accountability of model. Optimizing real-time deployment via edge computing and progressing rigidity against adversarial attacks is essential.

149 Investigation of seismic performance of reinforced concrete shear walls

Subrata Majee[1,a] and Nasar Ali R.[2]

[1]Assistant Professor, Department of Civil Engineering, Kalinga University, Raipur, India
[2]Department of Civil Engineering, Kalinga University, Raipur, India

Abstract: High-rise buildings frequently utilize shear wall systems because of their excellent seismic performance, adequate integrity, and force transfer. However, many shear wall constructions are no longer able to withstand natural disasters like earthquakes and can no longer satisfy the functional requirements due to inadequate Material durability, unconventional design, and the reality that some structures have outlived their intended use. Studying the seismic performance of shear wall constructions and reinforcing them are therefore important from a practical standpoint. This study examined the seismic performance of an RC shear wall that had some corrosion. Four shear wall specimens in all (W1, W2, W3, and W4) were created and put through a corrosion test. A 5% NaCl solution was utilized for the corrosion test. Shear deformation study, ductility analysis, and mass reduction in steel bars were performed on the corroded shear walls. The findings demonstrate that the size of the shear walls' hysteresis loop clearly reduces if the corroded section's height boosts the overall height from 18% to 23%. In contrast to the uncorroded shear wall, the unilaterally corroded shear wall exhibits a fat hysteresis loop, an elevated displacing ductility ratio and plastic rotation angle, and a comparatively sluggish stiffness deterioration.

Keywords: Seismic performance, RC shear wall, corrosion, ductility analysis, shear deformation analysis

1. Introduction

The three types of RC shear walls are squat wall, walls that are relatively thin, and thin walls based on the aspect ratio. 6 generally exhibit shear dominating responses, medium-slender walls commonly operate in the combined Shear and flexural reaction, and thin walls with aspect ratios more than 2. Additionally, the corrosion products' volume expansion decreases the degree of adhesion between the adjacent concrete and the steel framework and produces fractures in the parallel to the steel bars' axial direction [12–14]. Numerous studies have examined the seismic activity of reinforced concrete shear walls both pre- and post-corrosion to date [10–13, 15–19]. Applying the in-plane shear test to determine how the rate of steel corrosion affects the RC shear walls' shear strength into the seismic resilience of RC shear walls that have corroded [17]. In the event of precipitation and evaporation, chloride ions have a tendency to collect in the roots of structures. The phenomena of localized corrosion of reinforced concrete shear walls will result from these issues. The longer the duration of use for shear walls, the more likely it is that persistent local corrosion will result in concrete cracking and even spalling of the concrete cover [21]. This will cause the mechanical properties of steel bars to deteriorate, which will negatively impact the mechanical characteristics and seismic performance of shear walls. There are differences in the impacts of local and global corrosion on shear wall seismic performance, and current research cannot offer useful recommendations for squat shear walls that are locally corroded.

2. Materials and Methods

2.1. Test specimens

Four specimens of partly corroded reinforced concrete shear walls were created in order to investigate their seismic performance. The specimens have an aspect ratio of 1.0. The wall was 600 mm in width, 600 mm in height, and 100 mm in thickness. The concrete cover had a thickness of 10 mm. Table 149.1 lists the specific concrete mix percentage. 49.65 MPa was the concrete's 28-day cubic compressive strength. The steel bars that

were positioned inside the wall had a dia of 6 mm and a spacing of 150 mm. The longitudinal and horizontal reinforcement ratios of steel bar distributions in the body of wall specimens were 0.42% and 0.38%, respectively. With regard to the concealed columns' longitudinal reinforcement, the diameter and the reinforcement ratio were 12 mm and 4.52%, respectively. The stirrups of the concealed columns had the following dimensions: 6 mm in diameter, 150 mm in spacing, and 0.38% in reinforcement ratio.

3. Experimental Procedure

3.1. Corrosion test

Table 149.2 displays the various corrosion states of the shear wall specimens. An aqueous solution including 5% bulk fraction NaCl was pre-positioned at the specimens' planned corroded position.

Although steel corrosion may be accelerated in a short amount of time in a laboratory setting by using the continuous current approach, it is challenging to replicate the same corrosion properties in a natural setting. Some researchers discovered that the steel bars' resistance to corrosion was comparable to that of steel bars found in naturally occurring RC structures when 200 µA/cm2 or less was a current density throughout the process of rapid corrosion. Consequently, 180 µA/cm2 was chosen as the current density for this corrosion test.

For 72 hours, the specimens of RC shear walls were submerged in a solution of 5% NaCl prior to the accelerated corrosion test to guarantee complete interaction between the concrete and the sodium chloride solution and the formation of an enclosed circuit using

the steel bars. With a 0–30 V output voltage and a 0–5 A output current, a DC power supply was attached to the -Ve terminal of a copper rod that was inserted into the water tank. To hasten the corrosion process, the positive terminal of the DC power supply was linked to the steel bars that were 90 millimetres (W2 and W3) or 150 millimetres (W4) from the wall. The specimens' corrosion-induced cracking was seen during the corrosion test.

3.2. Quasi-static test

Following the accelerated corrosion test, the quasi-static test was performed on the RC shear wall specimens in the structural laboratory. To assess the specimens' potential to deform during loading, displacement meters with a 50 mm measurement range were installed on the L and R sides. The specimen was first subjected to a vertical force in order to achieve an ratio of axial compression of 0.1, which held true throughout the test. Next, a hydraulic actuator was used to apply a horizontal load that reciprocates and causes movement on the specimen. In the horizontal direction, the displacement increase was 1.4 mm with a displacement angle of 0.2%. During the initial cycles, increments of 0.1% and 0.05% were used for the displacement angle, corresponding to 0.35 and 0.7 mm for the horizontal displacement, in order to more accurately identify the cracking displacement. When the specimens' applied horizontal load fell to 85% of their maximal load or they became visibly damaged, the loading test was terminated.

3.3. Calculating the steel bar mass loss

Following the quasi-static test, the steel bars in the specimens were removed from the concrete by crushing them, and the mass loss of the steel bars was calculated. A 12% solution of hydrochloric acid was used to pickle the rusty steel bars after the steel bars were taken out of the sample and the concrete that was adhering to them was scraped. After neutralizing the steel bars with water containing lime, pure water was used to wash them, and then allowed to dry for four hours. The following equation was used to compute

Table 149.1. Concrete's mix proportion

Materials	Unit (kg/m³)
Cement	348
Fine aggregate	738
Coarse aggregate	1126
Water	165
Superplasticizer	7.6

Source: Author.

Table 149.2. Corrosion states of the shear wall specimens

Specimen ID	Side L Corrosion Time	Height of Corrosion / Side L's Total Height	Side R Corrosion Time	Height of Corrosion / Side R's Total Height
W1	0	0	0	0
W2	85 days	18%	0	0
W3	85 days	18%	85 days	18%
W4	85 days	23%	85 days	23%

Source: Author.

the typical mass reduction of steel bars in the specimens' corroded areas:

$$Lm = \frac{m_0 - m}{m_0} \times 100$$

Where, m and m0 = steel bar's masses prior to and during corrosion, respectively, Lm = mass reduction in a steel bar, percentage.

4. Results and Discussion

4.1. Examination of steel bar mass loss

Table 149.3 lists the mean mass reduction of the steel bars in the specimens' corroded areas. The typical mass reduction of steel bars is not significantly affected by the variation in the height of the corroded region between W3 and W4. This is due to the fact that the overall length of the corroded steel bars is the primary distinction between the corrosion of W3 and W4. It is clear that Bilateral corrosion is more complicated than unilateral corrosion alone when looking at W2 and W3 specimens within the same days of corrosion. Although there are some localized areas on this side of W2R where rust products have appeared, there is a very tiny quantity of rusted steel bars in comparison to the uncorroded steel bars, making it meaningless to calculate the steel bars' average mass loss. Some corrosion has been seen on the W2R steel bars that are situated distant from the water tank. Since W2R is receiving electricity during the corrosion test, W2 corrodes less than W3 because the current flowing through W2L's steel bars is less than anticipated.

4.2. Ductility evaluation

Ductility of a component to flex over time from allowing failure to occur (loading to its maximum), is one of the primary factors used to assess the structural capabilities in an earthquake. The shear walls' ductility increases with a larger change in ductility ratio. Positive and negative loading have different loads and displacements as a result of the Bauschinger effect, as Table 149.4 illustrates. Table 149.4 presents the results of the computation. Consequently, the following equations are used in this research to compute the changes in ductility ratios and the rotation angle.

$$\mu = \Delta u / \Delta y$$
$$\theta\,p = (\Delta u - \Delta y)/H$$

where
H = predicted the specimens' height;
μp = rotation angle
μ = displacement ductility ratio.

Comparing W3 and W4, it is discovered that when the corrode region rises from 18% to 23% of the overall height, respectively, the ratio of changes in ductility and rotational angle of the specimens both steadily decrease. The ratio of changes in ductility and rotational angle decreases by 47.1% and 35.8%, respectively, in the direction of +Ve loading and by 8.2% and 31.3%, respectively in the direction of -Ve loading.

In the direction of positive loading, W3 exhibits a reduction of 20.5% in the plastic rotational angle and 0.3% in the changes in ductility ratio when compared to W2. Negative loading is impacted by positive loading-induced damage, and while the plastic rotational angle continues to decrease, the changes in ductility ratio increases in the negative loading direction. In the direction of positive loading, W2's ratio of changes in ductility and rotational angle are increased by 37.9% and 30.7%, respectively, compared to the uncorroded W1, while in the direction of positive loading, they are raised by 14.5% and 16.8%, respectively.

4.3. Analysis of shear deformation

When the displacement meter is loaded to its full capacity, the specimen sustains considerable damage that renders the data useless. Shear strain, shear deformation ratio, yield, and cracking sites are the only metrics that are investigated.

The shear strain and the proportion of horizontal movement in relation to shear deformation of W2 decrease in direction of positive loading when contrast with the uncorroded W1. Shear strain variations and the proportion between horizontal displacement and shear deformation, however, are erratic in the negative loading direction. In the direction of positive loading, comparing W1, W3, and W4, the shear stress

Table 149.3. Steel bar average mass loss in the corroded region

Specimen ID	Corroded Side	Days of Corrosion	Corrosion Target Height in mm	Mean Mass Loss%
W1	—	0	0	0
W2	L	85	95	14.02
	R	0	0	0
W3	L and R	85	95	17.69
W4	L and R	85	145	18.01

Table 149.5. Shear stress and the proportion of horizontal displacement to shear deformation

Direction of Loading	Specimen ID	Cracking Point		Yield Point		Peak Point	
		γ	Δs/Δc (%)	γ	Δs/Δy (%)	γ	Δs/Δm (%)
Positive	W1	1.058	33.25	3.12	53.29	8.346	66.81
	W2	0.276	31.58	1.47	37.28	4.217	40.82
	W3	0.342	23.80	1.28	26.15	3.782	39.48
	W4	0.297	9.82	1.06	13.42	1.896	24.30
Negative	W1	1.210	36.21	2.35	43.10	6.628	55.36
	W2	0.571	28.42	3.58	44.80	6.829	50.31
	W3	0.143	9.38	0.86	16.53	4.290	42.35
	W4	0.186	9.76	0.83	16.72	3.120	35.29

Source: Author.

at the fracture site decreases by 67. 9% and 66%, and at the peak point by 54. The increases in corroded area correspond to increases in shear strain of 0 to 18% and 23% of the total height. In the negative loading direction, W3 and W4 exhibit lower shear strain at the cracking point of 88. 6%, and at the peak point of 35 in Table 149.5. When loading in a positive direction, W3 and W4 exhibit a reduction in the ratio of shear deformation to horizontal displacement at the cracking point of 28. 8%, and the peak point of 40. In the direction of negative loading, there is a reduction of 74% and 73% in the proportion of horizontal displacement to shear deformation of W3 and W4 at the cracking point, 61.

5. Conclusion

In this paper, Corroded RC shear walls' seismic performance has been investigated. The mass reduction of steel bars in rusted regions, with the average mass loss not significantly affected by the height difference between W3 and W4. The average mass loss is less in specimens with unilateral corrosion. W2R steel bars are not completely uncorroded, as W2 corrodes less than W3 due to less anticipated current flow. The changes in ductility ratio and rotational angle of specimens W3 and W4 decrease as the height of the corroded area increases. Positive loading results in a decrease of 47.1% and 35.8%, respectively, while negative loading results in an increase of 14.5% and 16.8%. Negative loading impacts the ratio and plastic rotation angle, affecting the loading direction. W2's shear strain decreases in positive loading directions compared to uncorroded W1 due to increased corrosion risk. Shear strain variations and ratios are erratic in negative loading directions. W3 and W4 show lower strain at cracking, yield, and peak points. Increased corrosion risk is due to distributed steel bars with thicker concrete covers.

150 Leveraging AI and blockchain in MANETs to enhance smart City infrastructure and autonomous vehicular networks

Uruj Jaleel[1,a] and R. Lalmawipuii[2]

[1]Associate Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: The integration of Artificial Intelligence (AI) and blockchain technology into Mobile Ad Hoc Networks (MANETs) holds significant promise for advancing smart city infrastructure and autonomous vehicular networks. This paper explores the synergistic potential of these technologies to address the inherent challenges of MANETs, such as scalability, security, and data integrity. AI techniques, including machine learning and reinforcement learning, are employed to optimize routing protocols, enhance data transmission rates, and reduce latency. Blockchain technology, leveraging Practical Byzantine Fault Tolerance (PBFT) and other consensus mechanisms, provides a secure and decentralized framework for data management, ensuring trust and integrity among network nodes. The application of these integrated technologies is particularly relevant for smart cities, which rely on real-time data collection and analysis for efficient management of urban operations such as traffic flow, environmental monitoring, and energy consumption. Autonomous vehicular networks, requiring robust communication and data exchange between vehicles and infrastructure, also benefit from the improved network performance and security afforded by AI and blockchain integration. Experimental analysis demonstrates significant improvements in key performance metrics. For instance, Sensor 2 achieved the highest data transmission rate of 12 Mbps, while Sensor 4 had the lowest at 9 Mbps. Latency measurements showed that Sensor 2 recorded the lowest latency at 45 ms, with Sensor 3 having the highest at 55 ms.

Keywords: Artificial Intelligence (AI), blockchain technology, practical byzantine fault tolerance (PBFT), mobile Ad Hoc networks (MANETs), autonomous vehicular networks

1. Introduction

The rapid urbanization and technological advancements of the 21st century have driven the evolution of smart cities, where the integration of cutting-edge technologies is essential to manage resources efficiently, ensure public safety, and improve the quality of life for citizens. At the heart of this transformation lies the deployment of robust communication networks capable of handling vast amounts of data generated by numerous interconnected devices and systems [1]. MANETs have emerged as a key enabler in this context due to their flexibility, self-configuring nature, and ability to operate without a fixed infrastructure [2]. However, MANETs face significant challenges, including issues related to scalability, security, and data integrity. To address these challenges, integrating AI and blockchain technology into MANETs presents a promising solution. AI techniques, such as machine learning and reinforcement learning, can optimize network performance by predicting and adapting to changing conditions, while blockchain technology provides a secure and decentralized framework for data management and transaction validation [3]. This integration is particularly pertinent in enhancing smart city infrastructure and autonomous vehicular networks [4]. Smart cities rely on real-time data collection and analysis to manage urban operations effectively, from traffic management and environmental monitoring to energy consumption and public safety [5].

Autonomous vehicular networks, on the other hand, require reliable communication and data exchange between vehicles and infrastructure to ensure safe and efficient transportation [6]. Exploring the synergistic potential of AI and blockchain in MANETs addresses the complex requirements of smart city applications and autonomous vehicular networks [7]. By leveraging AI's capabilities in optimizing routing protocols and blockchain's strengths in securing data exchanges, a more resilient, efficient, and scalable network infrastructure can be created [8]. The experimental analysis provides insights into key performance metrics such as data transmission rates, latency, and air quality monitoring, highlighting the practical benefits and areas for future improvement in deploying these technologies in real-world scenarios. This research contributes to the ongoing efforts in building smarter, more connected urban environments that can adapt to the evolving needs of modern cities [18]. The objectives are:

Implement AI algorithms, such as machine learning and reinforcement learning, to optimize routing protocols and improve data transmission rates and latency.

- Evaluate the effectiveness of PSO and other AI techniques in dynamically adjusting network parameters based on real-time conditions.
- Integrate blockchain technology into MANETs to provide a secure, decentralized framework for data management.
- Employ PBFT and other consensus mechanisms to ensure data integrity and trust among network nodes.
- Deploy MANETs augmented with AI and blockchain technologies to enhance the efficiency and reliability of smart city applications, such as environment monitoring, traffic management, and energy consumption.

2. Literature Review

The integration of AI and blockchain technology in MANETs is a rapidly evolving field that promises to revolutionize smart city infrastructure and autonomous vehicular networks [9]. MANETs are self-configuring, dynamic networks consisting of mobile nodes that communicate without fixed infrastructure [10]. They are critical for applications requiring rapid deployment and flexibility, such as disaster recovery, military operations, and increasingly, smart cities and autonomous vehicular networks [11]. However, MANETs face challenges related to scalability, reliability, and security due to their decentralized nature and dynamic topology. AI techniques, particularly machine learning and reinforcement learning, have been applied to address various issues in MANETs [12]. For example, AI can

optimize routing protocols by predicting network conditions and adjusting routes dynamically [17]. PSO and RL algorithms have shown promise in enhancing routing efficiency and network performance. PSO helps in optimizing path selection based on multiple criteria, while RL can adapt to changing network conditions and improve decision-making processes [13]. Blockchain technology, with its decentralized and secure nature, is increasingly being explored to address security and trust issues in MANETs. Blockchain can provide a tamper-proof ledger for recording transactions and interactions between nodes, enhancing trust and reducing the risk of malicious activities [14]. PBFT is one consensus mechanism that has been integrated into MANETs to ensure data integrity and consensus among nodes [15]. The combination of AI and blockchain in MANETs aims to leverage the strengths of both technologies to create a more robust and efficient network. AI can enhance the decision-making capabilities and adaptability of MANETs, while blockchain provides a secure and reliable framework for data exchange and transaction validation.

Research has shown that such integration can significantly improve network performance, security, and reliability, making it suitable for complex applications like smart cities and autonomous vehicular networks Smart cities rely on a vast network of interconnected devices and systems to manage resources, services, and infrastructure efficiently. MANETs, augmented with AI and blockchain, can support various smart city applications, including environmental monitoring, traffic management, and public safety [16]. For instance, wireless sensor networks (WSNs) deployed in MANETs can collect real-time data on air quality, traffic flow, and energy consumption, while AI algorithms analyze this data to optimize city operations. Autonomous vehicular networks require reliable communication and data exchange between vehicles and infrastructure. MANETs provide the necessary flexibility and coverage for such networks, and the integration of AI and blockchain can further enhance their capabilities. AI algorithms can optimize routing and traffic management, while blockchain ensures secure data sharing and coordination among autonomous vehicles. Despite the promising advancements, several challenges remain. Scalability and energy efficiency are critical concerns in MANETs, particularly with the increased computational demands of AI and blockchain. Future research should focus on developing lightweight protocols and energy-efficient algorithms. Additionally, real-world testing and deployment are essential to validate the effectiveness of these technologies in diverse urban environments. The integration of AI and blockchain in MANETs presents a transformative approach to enhancing smart city infrastructure

and autonomous vehicular networks. By addressing existing challenges and leveraging the strengths of these technologies, future research can pave the way for more efficient, secure, and resilient urban systems.

3. Proposed Work

3.1. Practical Byzantine fault tolerance

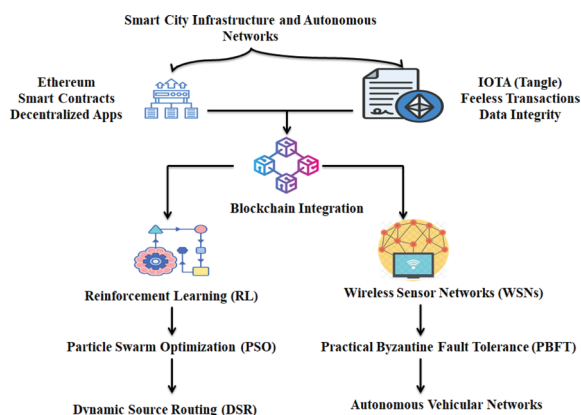
PBFT is pivotal for securing and optimizing distributed networks like MANETs, crucial in smart city infrastructure and autonomous vehicle networks. PBFT operates in three phases: pre-prepare, prepare, and commit. Here, nodes propose, validate, and confirm transaction blocks, requiring agreement from a majority of non-faulty nodes for consensus. This process ensures the integrity of the ledger, crucial for secure applications in smart grids, water management, and public safety. In vehicular networks, PBFT guarantees reliable communication, safeguarding against disruptions and malicious attacks that could compromise traffic systems and autonomous vehicle coordination. It upholds data integrity across IoT devices, crucial for accurate decision-making in traffic management and emergency response. For autonomous vehicles, PBFT ensures trustworthy data exchange, essential for real-time navigation and collision avoidance decisions. PBFT's efficiency in consensus ensures low-latency processing, ideal for real-time applications in autonomous driving and smart city operations. This scalability extends to vehicular networks, enabling robust communication and coordination without centralized control, thereby enhancing overall network reliability. Integrating PBFT in MANETs enhances security, reliability, and efficiency across smart city infrastructure and autonomous vehicle networks, leveraging AI and blockchain technologies for advanced, resilient systems in Figure 150.1.


Figure 150.1. Integrated framework for AI and blockchain in MANETs.

3.2. Particle swarm optimization

PSO draws inspiration from collective behavior in nature, such as bird flocking, to optimize parameters crucial for MANETs in smart city infrastructure and autonomous vehicular networks. PSO initializes a swarm of particles, each representing a potential solution, which adjusts its position based on individual and collective experiences. In MANETs, PSO optimizes routing protocols to enhance data transmission efficiency among IoT devices, sensors, and central systems. This improves real-time applications like traffic monitoring and energy management. PSO dynamically optimizes vehicular routing to minimize delays and congestion, crucial for reliable autonomous vehicle communication. It allocates resources efficiently across smart city services, balancing network load and computational tasks in edge computing environments, enhancing overall system performance. PSO adapts network configurations in MANETs to varying conditions, ensuring resilience and high performance amid changing traffic and environmental factors. Scalable and flexible, PSO handles large-scale deployments and diverse applications, adapting to dynamic vehicular network environments effectively. Integrating PSO in MANETs elevates performance, efficiency, and adaptability in smart city infrastructure and autonomous vehicle networks. It optimizes routing, resource allocation, and network configurations to deliver reliable, scalable systems that meet the demands of modern urban environments and autonomous driving applications.

Algorithm 1: PSO Algorithm for Enhancing Smart City Infrastructure and Autonomous Vehicular Networks in MANETs:

1. Define the problem and the objective function f(x) to be optimized.
2. Initialize a swarm of nnn particles with random positions and velocities in the solution space.
3. Set the maximum number of iterations T and the stopping criteria.
4. Calculate the fitness value $f(X_i)$ for each particle iii based on the objective function.
5. Identify the particle's best-known position
6. Identify the swarm's best-known position.
7. Update the velocity for each particle i using the formula
8. $V_{i,t+1} = \omega V_{i,t} + c_1 r_1 (P_{i,t} - X_{i,t}) + c_2 r_2 (g_t - X_{i,t})$
9. Repeat the evaluation and update steps until the stopping criterion is met (e.g., a maximum number of iterations TTT or a satisfactory fitness level is achieved).
10. Return the best solution found and the corresponding fitness value.

The PSO algorithm provides an effective method for optimizing various parameters in MANETs, contributing to enhanced smart city infrastructure and autonomous vehicular networks. By iteratively adjusting particle positions based on personal and collective experiences, PSO achieves a balance between exploration and exploitation, leading to efficient solutions for dynamic and decentralized network environments. This integration of PSO with AI and blockchain technologies can significantly improve the performance, scalability, and adaptability of modern urban systems and autonomous driving applications.

3.3. *Dynamic source routing*

DSR is a critical routing protocol designed for MANETs, enhancing smart city infrastructure and autonomous vehicular networks by enabling efficient communication among mobile nodes without fixed infrastructure. Its on-demand routing adapts dynamically to changing network topologies, crucial for the dynamic environments of smart cities and vehicular networks. DSR operates with route discovery and maintenance mechanisms: When a source node needs to send a packet to an unknown destination, it initiates a route discovery by broadcasting a Route Request. In smart cities, DSR efficiently routes data between IoT devices, sensors, and central systems, optimizing network resource use for applications like traffic management and emergency services. For autonomous vehicles, DSR ensures reliable communication by dynamically adapting routes to changing vehicular network topologies, critical for applications like navigation and collision avoidance. In vehicular networks, rapid adaptation optimizes communication paths, reducing latency for autonomous vehicle systems. Integration with blockchain enhances DSR's security in smart city networks, securing routing information with tamper-proof ledgers to prevent attacks like route manipulation. This integration ensures data authenticity and integrity, critical for secure autonomous vehicular operations. DSR enhances performance, reliability, and adaptability in MANETs for smart city infrastructure and autonomous vehicles. This makes DSR pivotal in leveraging AI and blockchain for robust urban network solutions and advanced autonomous driving applications in Figure 150.2.

3.4. *Implementation*

Meanwhile, IOTA's feeless and scalable Tangle technology supports high-frequency micro-transactions essential for real-time data sharing among autonomous vehicles, ensuring efficient and secure communication in dynamic urban environments. RL algorithms adapt traffic management systems in smart cities by dynamically adjusting signal timings based on real-time traffic

data, thereby reducing congestion and enhancing traffic flow efficiency. WSNs play a fundamental role by providing real-time data collection and transmission capabilities in smart city environments. WSNs facilitate critical data aggregation for decision-making processes in smart city operations, enhancing urban planning, resource allocation, and environmental management. PBFT safeguards data integrity in smart city infrastructures by securing communications between WSN nodes and central servers, ensuring the accuracy and trustworthiness of collected data. In autonomous vehicular networks, PBFT enhances network security by validating transactions and maintaining consistent network views among vehicles, critical for safe and efficient autonomous driving. In smart cities, PSO enhances the placement of WSN nodes and optimizes data routing paths, maximizing coverage and efficiency. DSR further enhances communication reliability in MANETs by enabling nodes to dynamically discover and maintain efficient communication routes. DSR supports smart city operations by ensuring seamless data transmission between WSN nodes and central systems, even amidst fluctuating network conditions. In autonomous vehicular networks, DSR enables vehicles to dynamically adjust routes based on real-time traffic and environmental conditions, ensuring continuous and reliable communication essential for safe and efficient autonomous driving.

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha[R_{t+1} + \gamma max_a Q(s_{t+1}, a) - Q(s_t, a_t)] \quad (1)$$

The equation represents the Q-learning update rule in reinforcement learning. Here, is updated based on the observed reward received after taking action in state, adjusted by the learning rate α\alpha$\alpha$ and the discounted future rewards. This iterative process allows the agent to learn the optimal policy by updating its estimates of action values according to the experienced rewards and future expected rewards in subsequent states.

$$V_{i,t+1} = \omega V_{i,t} + c_1 r_1 (P_{i,t} - X_{i,t}) + c_2 r_2 (g_t - X_{i,t}) \quad (2)$$

The equation represents the velocity update rule in PSO. Here, denotes the velocity of particle i at iteration t, ω is the inertia weight maintaining particle momentum, and are acceleration coefficients governing particle movements towards its personal best and the global best, respectively. The random variables and adjust the influence of personal and global bests, ensuring exploration and exploitation to optimize the search space effectively in PSO algorithms.

4. Results

The devices are configured to communicate wirelessly through MANET protocols such as DSR, ensuring

dynamic and adaptive routing capabilities. Additionally, autonomous vehicles are equipped with communication modules and onboard processing units capable of executing AI algorithms and interacting securely with blockchain networks like Ethereum and IOTA. The integration of Ethereum and IOTA involves deploying blockchain nodes and smart contracts to manage and secure transactions and data exchanges within the MANETs. Smart contracts are programmed to automate and enforce agreements between smart city services and vehicles, ensuring data integrity and transparency. PBFT mechanisms are implemented to safeguard against malicious attacks and ensure consensus among distributed nodes. Data collection from WSNs and vehicle-to-vehicle (V2V) communication data are simulated to assess the performance of AI-driven algorithms like RL and PSO. RL algorithms optimize traffic flow and resource allocation, while PSO optimizes network parameters such as routing and energy consumption.

The graph depicts the latency measured in milliseconds (ms) by different sensors. Latency represents the delay between data transmission initiation and its reception, crucial for assessing network responsiveness and performance. Sensor 3 exhibits the highest latency at 55 ms, indicating the longest delay among the sensors plotted. Sensors 1 and 4 both show relatively lower latencies of 50 ms and 48 ms, respectively, suggesting quicker data transmission and response times compared to Sensor 3. Sensor 2 records the lowest latency at 45 ms, indicating the most responsive network performance among the sampled sensors. Sensor

5 falls in between with a latency of 52 ms. These latency variations across sensors reflect differences in network conditions, traffic loads, and communication efficiencies within the smart city infrastructure. Lower latencies generally signify faster data transmission and improved network responsiveness, crucial for real-time applications and seamless connectivity. The graph provides a comparative view of latency metrics across different sensors, highlighting their respective performance in terms of data transmission speed and network responsiveness. Monitoring and optimizing latency levels are essential for enhancing overall system efficiency, ensuring reliable communication, and supporting the effective deployment of smart city technologies.

Figure 150.3 illustrates the data transmission rate in megabits per second (Mbps) recorded by different sensors. It provides a comparative view of how efficiently each sensor transfers data within its network environment. Sensor 2 exhibits the highest data transmission rate at 12 Mbps, indicating optimal data transfer capabilities compared to the other sensors. Sensors 1 and 5 both show a data transmission rate of 10 Mbps, representing consistent performance in data transfer. Sensor 3 records a rate of 11 Mbps, while Sensor 4 has the lowest transmission rate at 9 Mbps. These variations in data transmission rates across sensors suggest differences in network conditions, bandwidth availability, or operational efficiencies within the smart city infrastructure in Table 150.1. The graph highlights Sensor 2 as the most efficient in data transmission, while Sensors 4 and 1 demonstrate lower

Table 150.1. Performance metrics of sensor

Sensor ID	Temperature (°C)	Humidity (%)	Traffic Flow (vehicles/hour)	Energy Consumption (kWh)
1	25.3	65	1200	35.2
2	23.8	70	1100	31.5
3	27.1	62	1150	33.8
4	24.5	68	1250	34.6
5	26.0	67	1180	32.9

rates, potentially influenced by network congestion or resource allocation. The graph provides insights into the data handling capabilities of each sensor, essential for optimizing network performance and ensuring reliable data communication in smart city applications. Monitoring and analyzing these transmission rates help in assessing network health, identifying potential bottlenecks, and enhancing overall system efficiency for better service delivery and data-driven decision-making.

Figure 150.4 visualizes the time in seconds recorded by different sensors. Sensor 1 shows a time measurement of approximately 3600 seconds, which is the lowest among the sensors plotted. Sensor 2 records around 7200 seconds, indicating a longer duration compared to Sensor 1. Sensor 3 measures about 10800 seconds, continuing the trend of increasing time durations. Sensor 4 and Sensor 5 record approximately 14400 seconds and 18000 seconds, respectively, marking the highest time durations among the sensors. The gradual increase in time measurements from Sensor 1 to Sensor 5 suggests potential differences in operational cycles or periods of activity for each sensor. This could reflect varying patterns in data transmission, energy consumption cycles, or periodic reporting intervals
Figure 150.4. Time of different sensors.

within a smart city infrastructure or network environment. The graph provides a comparative view of time measurements across different sensors, highlighting their respective operational timelines or durations over the specified period. Such insights are crucial for monitoring and managing sensor deployments effectively, ensuring continuous data collection and system performance optimization in smart city applications.

Figure 150.5 illustrates the Air Quality Index (AQI) recorded by different sensors across a smart city environment. The AQI values range from 38 to 45, indicating varying levels of air pollution and quality. Sensor 4 recorded the highest AQI of 45, suggesting poorer air quality compared to the other sensors. Sensors 1, 3, and 5 show relatively moderate AQI values around 40 to 42, indicating slightly better air quality in those areas. Sensor 2 recorded the lowest AQI of 38, suggesting the best air quality among the sampled locations. This dataset reflects dynamic environmental conditions across different parts of the city, influenced by factors such as vehicular traffic, industrial activities, and weather patterns. Monitoring AQI using IoT sensors helps in understanding air pollution levels, facilitating informed decision-making for urban planning, public health measures, and environmental policies aimed at improving overall air quality and citizen well-being.

5. Conclusion

The integration of AI and blockchain technologies in Mobile Ad Hoc Networks demonstrates significant potential for enhancing smart city infrastructure and autonomous vehicular networks. Sensor 2 exhibited the highest data transmission rate of 12 Mbps, showcasing optimal data transfer capabilities that are essential for real-time communication and efficient network operations. On the other hand, Sensor 4, with the lowest data transmission rate of 9 Mbps, suggests areas for potential optimization to ensure consistent network performance across all nodes. Sensor 2 recorded the lowest latency at 45 ms, highlighting its superior performance in ensuring rapid data transmission. Conversely, Sensor 3 had the highest latency of 55 ms, pointing to potential delays that could affect time-sensitive applications in smart city environments. Such environmental monitoring is crucial for public health and urban planning, ensuring that smart city initiatives can respond dynamically to changing conditions. These findings underline the importance of leveraging advanced technologies like AI and blockchain in MANETs to enhance data transmission efficiency, reduce latency, and provide real-time environmental monitoring. By addressing the variability in network performance and environmental conditions, smart city infrastructure can be optimized to support more

reliable and efficient autonomous vehicular networks. Future research should aim to develop and implement advanced algorithms that can handle the scalability issues of MANETs as the number of nodes increases. This includes optimizing data transmission rates and reducing latency across a larger network.

Abstract: The chatbot is been developed for personal assistance. This paper explores the application of Deep Learning in the development of chatbot systems. With the help of AI, Chatbots occurred as powerful tools for human-computer interaction across various domains. This study delves into underlying principles of Deep Learning and Neural Networks, examining how they are enabling chatbots to comprehend Natural language, generate contextually relevant responses, and improve user engagement by analyzing recent advancements in natural language processing techniques, including sequence-sequence models, attention mechanisms, and transformer architectures. This paper highlights the evolution of chatbot technology. Furthermore, it discusses challenges such as data scarcity, model interpretability, and ethical considerations, while proposing potential solutions and future research directions. This paper aims to provide perceptions into the modern techniques and best practices for developing effective chatbots using Deep Learning and Neural Networks.

Keywords: Chatbot, natural language processing (NLP), sequence-to-sequence models, attention mechanism, models interpretability, ethical considerations

1. Introduction

Facilitated by the rapid advancements in Deep Learning and Neural Networks, these systems optimize the convergence of artificial intelligence and natural language processing, reshaping the dynamics of human-computer engagement. This paper embarks on a comprehensive exploration of the transformative role played by Deep Learning [1] and Neural Networks in the evolution of chatbot technology, and their applications in personal assistance. The inception of chatbots is a paradigm in human-computer interaction, harnessing the power of Deep Learning, these systems exhibit an unprecedented ability to comprehend and interpret natural language inputs, thereby enhancing their efficiency as virtual assistants across diverse domains. Neural Networks, serving as the backbone of these chatbot architectures, facilitate the understanding of user queries, enabling the generation of contextually relevant responses in real time. At the heart of this study lies an in-depth examination of the underlying principles driving the efficiency of Deep Learning and Neural Networks in chatbot development. Through a synthesis of theoretical insights and empirical evidence, the mechanism of Deep Learning and Neural Networks empower chatbots to transcend more information retrieval and engaging interactions with the user. To discourse this exploration of recent advancements in natural language processing techniques, which have catalyzed the evolution of chatbot technology. The journey toward harnessing the full potential of Deep Learning and Neural Networks [2–4] in chatbot development is not devoid of challenges. The paper endeavors to provide a widespread study of the contemporary techniques and the best practices for developing effective chatbots using Deep Learning and Neural Networks. Through a holistic understanding of the interplay between technology and human interaction, we aim to the realization of more intelligent, and empathetic chatbot systems.

2.1. Ethical consideration

Human-machine intelligence (AI) over time, chatbots have grown in popularity and have been utilized to

---

help with a variety of activities, give information, and enhance customer service. But as AI chatbots proliferate, moral questions must be answered. The question of whether AI chatbots should be held responsible for their acts emerges as these machines grow increasingly complex and clever. Additionally, there are security and privacy problems with the data that AI chatbots gather and examine, particularly when it comes to vulnerable populations like the elderly and children. Concerns have also been raised regarding the possibility that AI chatbots will reinforce societal prejudice and bigotry.

Key points to consider: *Transparency:* AI chatbots ought to be open and honest about their goals, limitations, and capabilities. Users are entitled to information about whether they are communicating with a computer or a human, as well as what sort of data is being gathered and processed.

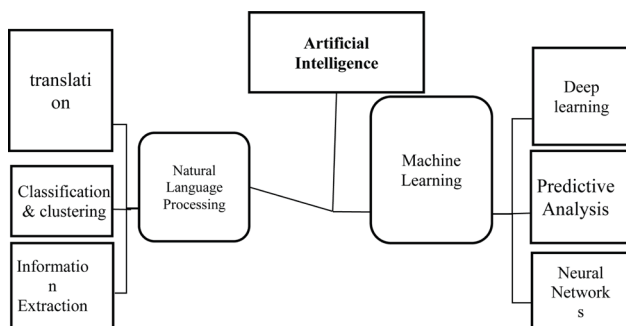
- *Privacy and Security:* AI chatbots must to be considerate of users' privacy and safeguard their information from misuse or illegal access. It is imperative for developers to implement protocols that guarantee the security and adherence to pertinent regulations of the data gathered by AI chatbots.
- *Bias and Discrimination:* AI chatbots should be created with the goal of preventing the reinforcement of societal prejudice and discrimination. It is important for developers to take precautions against stereotypes and prejudices that AI chatbots may perpetuate.
- *Accountability:* AI chatbots should be created with the goal of preventing the reinforcement of societal prejudice and discrimination. It is important for developers to take precautions against stereotypes and prejudices that AI chatbots may perpetuate.
- *Human Oversight:* Human oversight is necessary to make sure AI chatbots are functioning morally and efficiently. Human oversight can assist in locating and resolving any potential biases, mistakes, or moral dilemmas in Figure 151.1.


Figure 151.1. Simple structure of artificial intelligence.

2.2. *Deep learning*

The many layers a neural network builds up over time the more layers it has, the better it performs are what make deep learning "deep". The input data at each layer of the network is processed in a certain way, which provides information to the layer below it. A subset of machine learning called deep learning makes use of algorithms designed to mimic the workings of the human brain. Deep neural networks are used in many applications, such as chatbots that use deep resources to provide answers to queries. Machine learning, a subset of artificial intelligence, includes deep learning. Since the 1950s, the aim of artificial intelligence has been to make computers capable of thinking and reasoning in a manner akin to that of humans. The goal of machine learning is to train machines to think for themselves without explicitly programming them. Beyond machine learning, deep learning creates increasingly complex hierarchical models that mimic how humans process new information. Generally speaking, the original purpose of AI was to enable machines to perform tasks that would otherwise need human intelligence. The goal of deep learning is to make machine learning more efficient.

2.3. *Neural network*

Neural networks are relatively straightforward to comprehend since, at their core, they operate much like the human brain. After using deep hidden layers to learn about the network's interconnected neurons or nodes, the information travels between them. An output neuron layer then receives the answer and provides the final prediction or conclusion. Hemalatha et al. [1–3] describe an example of a machine learning system is an artificial neural network, which takes in input and uses examples and its own expertise to help the computer produce an output. Neural networks and algorithms are used by machines to help them learn and adapt without requiring reprogramming. Neural networks are models of the human brain in which each node or neuron is in charge of handling a certain portion of the problem. Until the network's connected nodes are able to generate an output and resolve the problem, they impart their knowledge and experience to the other neurons in the network. Trial and error plays a major role in neural networks and is necessary for the nodes to learn. Neural networks differ from computational statistical models, which are designed to learn about the relationship between variables, and computational machine learning, which is intended to produce accurate predictions, in that neural networks can learn from new data.

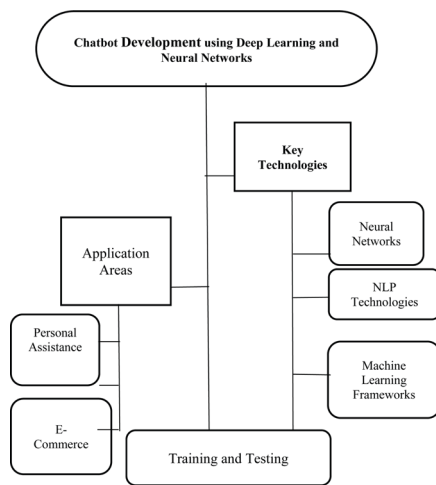
Neural network: There are many elements to a neural network that help it work, including: *Hidden layers:* These are densely packed with neurons, and a neural network may contain numerous hidden layers in Figure 151.2.


Figure 151.2. Development of chatbot in various sectors and their advancements.

Source: Author.

- *Output layer:* After the data has been divided up and processed through all of the hidden levels, this is the outcome.
- *Synapse:* This is how neurons and layers in a neural network are connected.

Together, these components form a neural network that aids in problem solving and prediction. An input is received by the input layer's input neurons, and then synaptic connections transfer the data to the buried layers. Each node in a separate layer is connected to every other neuron in a hidden layer. When a neuron receives information, it sends it on to the next neuron that is connected. Algorithms are essential for breaking down the data. A mathematical activation function determines how much information, or weight, it conveys, and the function's output is a number between 0 and 1. In addition, each layer computes a bias as a component of the activation function. The input for the next concealed layer, up until the output layer, is the activation function's end result. In order to respond to the query or provide a forecast, the final output in the output layer will be either 0 or 1, true or false.

2.4. NLP (Natural Language Processing)

NLP employs a wide range of methods to give computers the same level of natural language comprehension as people. Natural language processing uses artificial intelligence (AI) to analyze and interpret real-world data in a way that a computer can comprehend, regardless of whether it is spoken or written. Computers have microphones to record audio and programs to read, just as people have various senses like ears and vision. Similar to how humans' brains process information, computers use programs to process the inputs

they receive. Processing eventually converts the input into machine-understandable code.

- *Data preprocessing:* In order for machines to interpret text data, it must first be cleaned and prepared. Preprocessing organizes data into a comprehensible structure and draws attention to textual aspects that can be used by an algorithm. There are several ways to go about doing this, including the following:
- Tokenization: Words that whenever frequent terms are removed from the text, the words that best express the content are retained.
- Lemmatization: Lemmatization is the process of grouping together several forms of an inflected word. For instance, to process, the word "walking" would be reduced to its stem, or root form.

2.5. Attention mechanisms

The attention mechanisms in chatbots play a critical role in enhancing the accuracy and effectiveness of chatbot interactions. The underlying concepts of generative AI and language models, provide the foundation for attention mechanisms in chatbots. Attention mechanisms enable chatbots to prioritize and focus on relevant parts of a conversation, improving their ability to generate accurate and contextually appropriate responses. Generative AI and language models form the backbone of attention mechanisms in chatbots, providing a framework for chatbots to understand and respond to natural language inputs. Attention mechanisms are crucial in enhancing the responsiveness and accuracy of chatbot interactions, ensuring that users receive a personalized and seamless experience. Now that we have a better understanding of attention mechanisms and their role in chatbot development, let's delve into how they can be leveraged to improve chatbot performance. By prioritizing relevant parts of a conversation, attention mechanisms enable chatbots to generate more accurate and contextually appropriate responses.

2.6. Model interpretability

A machine learning algorithm's interpretability is a measure of how easy it is for people to understand the steps it takes to reach the results it does. Artificial intelligence (AI) algorithms have a reputation for being "black boxes" up until recently. This means that stakeholders and regulatory bodies have difficulty understanding the inner workings of these algorithms and the insights they produce. Certain models—like logistic regression, for example—are thought to be very simple and easy to comprehend, but interpretability becomes increasingly challenging as features are added or when more complex machine learning models—like deep learning—are used.

3. Proposed Methodology

Deep learning Models [2] are capable of recognizing data patterns with complex text as well as sounds for prediction. The code creates a bag-of-words representation for each document, where each word in the vocabulary is represented by a binary value indicating its presence in the document. This representation is used to train a neural network model. The neural network model architecture consists of densely connected layers with dropout regularization to prevent overfitting. The model is trained using stochastic gradient descent (SGD) with categorical cross-entropy loss. During training, the model learns to classify input text into one of the predefined intent classes. Training data is shuffled to ensure randomness and avoid bias. Once training is complete, the model is saved to a file for future use. This file contains the trained weights and architecture of the neural network. Overall, the methodology involves data preprocessing, model training, and model evaluation, resulting in a trained chatbot capable of understanding and responding to user input based on predefined patterns and intents.

As it involves multi-layered algorithms as neural networks it can perform responses relative to the user input. As it involves a training part, here JSON file, consists of a set of trained intents with tags, the type or patterns of words, and their respective responses to it. Also, the training parts are divided into batches and the batches are fed into model-completing epochs with the algorithms in neural networks. This first takes the user input and lemmatizes (takes the input as a root word or pattern) and divides the inputs as tokens without symbols. Then the tokens are taken in byte streams as 0s and 1s through a process called pickling. This pickling produces words and classes as a.pkl file which is later used in the model. From the training algorithms made, the inputs are checked for probability ranging from 0 to 1 and the most probable tag for the specified input pattern text is considered in Figure 151.3. Also, it includes a level called threshold confidence level, and the learning rate is given at 0. Training this model includes many tags and their responses and a trained model can perform assistance and guidance for the user input with a high level of accurate responses. Though a well-trained chatbot using our method is capable of producing relevant responses, it's not accurate to all the fields of input.
NLTK: Natural Language Tool Kit is used to check the matching operation of simple patterns and helps to produce relevant responses.

Tensor flow: This is used to train the neural networks which is an open-source machine learning library

TFlearn: Uses both the Tensor flow as well as NLTK as a deep learning library. TFlearn is a modular and

Transparent Deep learning library built on top of Tensorflow.

Algorithm:
1. Import necessary libraries: random, numpy, JSON, pickle, nltk, WordNetLemmatizer, and tensor flow.
2. Load intents from 'intents.json'.
3. Load words and classes from 'words. pkl' and 'classes. pkl'.
4. Load the pre-trained model from 'chatbot model.h5'.
5. Define a function clean_up_sentence (sentence) to tokenize and lemmatize the input text.
6. Define a function bow (sentence, words, show_details=True) to convert a sentence into a bag-of-words representation.
7. Define a function predict_class(sentence) to predict the intent of the input sentence using the trained model.
8. Define a function get_response (intents_list, intents_json) to get a response based on the predicted intent.
9. Print "ready to go" to indicate readiness.
10. Enter an infinite loop for user input.
11. Accept user input (message), Predict the intent of the input message using predict class().
12. Store the result in ints.
13. Get a response based on the predicted intent using get_response() and store it in res.
14. Print the response (res).
15. End of the loop.

4. Experimentation and Results

Intents Dataset (intents.json): This dataset contains predefined intents, along with patterns (phrases or sentences) and their corresponding responses. Each intent has a tag for identification.

- *Words Dataset (words. pkl):* This dataset is created from the patterns in the intent dataset. It consists of unique lemmatized words extracted from the patterns, excluding certain punctuation characters like '?', '!', '.', and ','.

Figure 151.3. Methodology of the neural network.

Source: Author.

- *Classes Dataset (classes. pkl):* This dataset contains unique intent tags extracted from the intents dataset in Figure 151.6.
- *Training Dataset:* The training dataset is dynamically created based on the intent dataset. For each pattern in the intents, it generates a bag-of-words representation and associates it with the corresponding intent tag. This dataset is then shuffled for training the model in Figure 151.7.

4.1. Performance analysis

Accuracy: Accuracy [1] is defined as the correct prediction of a Machine learning for its outcome.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

Loss: loss is defined as the measurement of how good a Neural Network model is in performing certain tasks.

$$MSE = \frac{1}{N} \sum_i^N (Y_i - \widehat{Y_i})^2$$

5. Results

The bot provided a 90.7% accuracy rate. The bot answered most of the questions accurately, but there were a few that were not, either because the bot did not have enough training or because the answer was incomprehensible to it in Figure 151.4. The bot predicted the answer and It was displayed on the window as shown in Figures 151.6–151.7) also the predicted answer was conveyed to the user. Overall the Chatbot has performed very well as expected in Figure 151.5.
Figure 151.4. Performance graph for loss prediction.

Source: Author.

Source: Author.

Figure 151.6. Output 1 after training the model.

Source: Author.

Figure 151.7. Output 2 after training the model.

Source: Author.

6. Conclusion

From our vantage point, chatbots are intelligent assistants that use artificial intelligence to transform business. A variety of chatbot-building platforms are available for different industries, including e-commerce, retail, banking, leisure, travel, health care, and so forth. Compared to people, chatbots are more efficient and can connect with a wider audience on messaging apps. They might soon become an effective information-gathering tool.

152 Optimizing agricultural water management through IoT-enabled smart irrigation system

Rajeev Kumar Bhaskar[1,a] and Balasubramaniam Kumaraswamy[2,b]

[1]Assistant Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: IoT-driven smart irrigation minimizes water waste by adjusting irrigation precisely to soil conditions, crucial for sustainable agriculture in water-scarce areas. Automated irrigation improves crop yield by ensuring optimal water levels, supporting healthier plant growth, and maximizing agricultural output. The smart irrigation system integrates IoT devices, MQTT communication, and user interfaces to enhance agricultural water management. Soil sensors, connected to microcontrollers like Arduino or ESP8266, monitor soil conditions and transmit data via MQTT to a cloud-hosted broker. This MQTT broker manages data storage, analysis, and facilitates real-time notifications and commands to optimize irrigation schedules. Users access the system through web or mobile interfaces to monitor soil moisture levels and receive alerts for timely interventions. The system's automated controls ensure efficient water use by activating irrigation pumps based on real-time sensor data, thereby minimizing water wastage and maximizing crop yield. By leveraging IoT technology and data analytics, the system provides farmers with actionable insights and predictive capabilities, enhancing decision-making and overall farm productivity. This integrated approach underscores the benefits of IoT in agriculture, offering scalable solutions for sustainable water management and improved agricultural outcomes. These findings highlight MQTT's role in enhancing agricultural productivity through scalable, adaptive, data-driven approaches, crucial for sustainable farming and profitability.

Keywords: IoT devices, MQTT communication, soil sensors, ESP8266, sustainable water management, scalable architecture decisions

1. Introduction

By leveraging advanced sensors and sophisticated data analytics, smart irrigation systems meticulously apply the exact amount of water required, significantly reducing water waste [1]. By delivering the optimal amount of water, these systems ensure that plants grow healthily, with a reduced risk of diseases caused by inconsistent watering. Environmental benefits are another critical aspect of smart irrigation systems. By minimizing runoff and reducing the leaching of fertilizers into nearby water bodies, smart irrigation systems help mitigate environmental pollution [6]. The convenience and control offered by smart irrigation systems cannot be overstated. This level of control ensures that the irrigation system can be fine-tuned to meet the specific needs of different plants and landscapes, enhancing overall effectiveness [8]. Smart irrigation systems are also highly scalable and customizable. This scalability ensures that the benefits of smart irrigation can be realized across different contexts and applications [9]. In addition to these benefits, smart irrigation systems assist in regulatory compliance. Smart irrigation systems can help property owners meet these regulations by ensuring efficient and responsible water use.

2. Literature Survey

Traditional irrigation techniques, while having served agriculture for centuries, come with several limitations that make them less efficient and more resource-intensive compared to modern alternatives [17]. One common method is surface irrigation, which involves flooding fields with water. Although simple and cost-effective, this technique often results in significant water wastage

due to evaporation and runoff, as well as uneven water distribution, which can lead to waterlogging and soil erosion [11]. Another traditional method is sprinkler irrigation, where water is sprayed over plants through a network of pipes and sprinklers. While more controlled than surface irrigation, it still suffers from high evaporation rates and can be inefficient in windy conditions. Drip irrigation, which delivers water directly to the plant roots, is more efficient but can be labor-intensive to set up and maintain, especially over large areas [12]. Given these limitations, the shift towards smart irrigation systems offers numerous compelling advantages.

Smart irrigation systems utilize advanced technology, such as soil moisture sensors, weather data integration, and automated control systems, to deliver water precisely where and when it is needed. This precision not only conserves water by minimizing waste but also ensures that plants receive consistent and optimal hydration, promoting healthier growth and reducing the risk of diseases associated with over or under-watering [13]. Additionally, smart irrigation systems can be managed and monitored remotely, providing unparalleled convenience and control for users. This allows for real-time adjustments based on current environmental conditions, further enhancing water use efficiency. Moreover, smart irrigation systems are highly scalable and customizable, making them suitable for various applications, from small gardens to vast agricultural fields [14]. They can be integrated with other smart technologies, such as weather stations and home automation systems, creating a cohesive and efficient ecosystem.

This integration supports sustainable water management practices, which are crucial in addressing the global challenge of water scarcity. By reducing runoff and minimizing the leaching of fertilizers into water bodies, smart irrigation systems also contribute to environmental protection and sustainability [15]. In contrast to the labor-intensive and less efficient traditional methods, smart irrigation systems represent a modern solution that aligns with both economic and environmental goals. They help reduce operational costs through lower water bills and decreased labor requirements, while also ensuring compliance with local water conservation regulations. The transition to smart irrigation is not just a technological upgrade but a necessary step towards more sustainable and efficient agricultural practices, making it an essential choice for the future of water management.

3. Proposed Work

In a smart irrigation system utilizing IoT technology, the architecture is structured around the integration of IoT devices, an MQTT (Message Queuing Telemetry Transport) broker, and user interfaces such as laptops or mobile devices in Figure 152.1. The IoT devices, furnished with soil temperature and humidity sensors,

continuously monitor the environmental conditions of the agricultural field. Functioning as MQTT clients, these devices transmit the collected data to an MQTT broker, which serves as a central hub managing communication across the system.

The MQTT broker, often hosted on a cloud platform, receives the data from the IoT devices and performs various tasks, including data storage, analysis, and processing. It also facilitates the dissemination of actionable insights and notifications. Users can access the MQTT broker via their laptops or mobile devices to receive real-time updates on soil conditions and irrigation requirements. Additionally, the broker can transmit commands back to the IoT devices to autonomously regulate water pumps, thereby ensuring optimal irrigation based on sensor data. This architectural framework enables efficient, real-time monitoring, and control of irrigation systems, leading to improved water management and enhanced agricultural productivity. Leveraging the lightweight nature of the MQTT protocol, the system minimizes bandwidth consumption and ensures robust communication, making it well-suited for IoT applications in smart agriculture.

The implementation of a smart irrigation system in agriculture involves a multi-layered approach, leveraging IoT technologies, data analytics, and automated controls to optimize water usage. As in Figure 152.2, system begins with the deployment of soil temperature and humidity sensors strategically placed throughout the agricultural field. These sensors continuously monitor soil conditions, providing critical data on temperature and moisture levels. The soil temperature and humidity sensors are the primary data acquisition tools. These sensors are connected to a microcontroller, such as an Arduino or ESP8266, which collects and processes the data. The microcontroller is programmed to read sensor data at regular intervals, ensuring continuous monitoring of soil conditions. This setup allows for real-time data collection, providing a granular view of the soil environment. The collected data is then transmitted via the MQTT protocol to a cloud-based IoT platform. MQTT (Message Queuing Telemetry Transport) is chosen for its lightweight nature and efficiency in low-bandwidth environments, making it ideal for
Figure 152.1. MQTT architecture.

Source: Author.

agricultural applications where internet connectivity may be limited. The microcontroller, equipped with a Wi-Fi module, publishes the sensor data to specific MQTT topics, which are received by an MQTT broker such as Mosquitto. The broker then forwards the data to the cloud IoT platform, ensuring seamless data transmission and aggregation. Once the data reaches the cloud IoT platform, it is stored in a database, such as InfluxDB, designed for time-series data.

The platform utilizes data analytics tools, such as Google BigQuery or AWS Lambda, to process the incoming data and derive actionable insights. These tools analyze the data to identify trends and patterns, such as variations in soil moisture and temperature over time. By integrating machine learning models, the system can predict irrigation needs based on historical data and weather forecasts, providing predictive analytics to optimize irrigation scheduling. A user-friendly interface is crucial for farmers and agricultural managers to access and utilize the system effectively. This interface is provided through a web dashboard and a mobile application, which display real-time data and analytics results. The dashboard visualizes soil conditions, historical data trends, and predictive analytics, offering an intuitive and comprehensive view of the field's status. Users can also receive notifications about critical events, such as low soil moisture levels, via SMS or email alerts, prompting timely irrigation actions to prevent crop stress and optimize water usage. The system includes an automated irrigation control mechanism, which activates a pump based on predefined soil moisture thresholds. When the soil moisture level drops below a certain point, the system triggers the pump to irrigate the field until the optimal moisture level is restored. This automation ensures precise and efficient water usage, reducing waste and enhancing crop yield. The integration of automated controls with real-time data monitoring and predictive analytics creates a robust and adaptive irrigation system.

Algorithm 1: IoT-Based Smart Irrigation System

1. Initialize sensor (DHT11) and GPIO (GPIO 4)
2. Initialize MQTT client
3. While True:
4. Read humidity and temperature using `read_retry`
5. If readings are valid:
6. Encrypt and publish data via MQTT
7. If humidity < threshold:

9. Else:
10. Deactivate irrigation
11. Else:
12. Log error and retry
13. Sleep for 1 minute

The system begins by initializing the necessary components. The DHT11 sensor is selected for monitoring temperature and humidity, and a specific GPIO (General Purpose Input/Output) pin on the microcontroller Raspberry Pi is designated for sensor connection. An MQTT client is also initialized to facilitate data transmission over the internet. Once the setup is complete, the system enters a continuous monitoring loop. This loop ensures that environmental data is regularly collected and processed. The read_retry method from the Adafruit_DHT library is used to obtain humidity and temperature readings from the DHT11 sensor. This method attempts to read the sensor up to 15 times, ensuring reliable data acquisition even in the face of occasional read failures. After obtaining the sensor readings, the system validates the data. Valid readings are essential for making informed decisions. If the readings are valid (i.e., neither is None), the data is encrypted for security purposes and then published to an MQTT broker. Encryption ensures that the data remains secure during transmission, protecting it from potential interception or tampering. The core functionality of the smart irrigation system is its ability to make real-time decisions based on humidity levels. The system checks the current humidity against a predefined threshold. If the humidity level is below this threshold, indicating dry conditions, the irrigation system is activated to water the plants. Conversely, if the humidity level is adequate, the irrigation system remains inactive to conserve water.

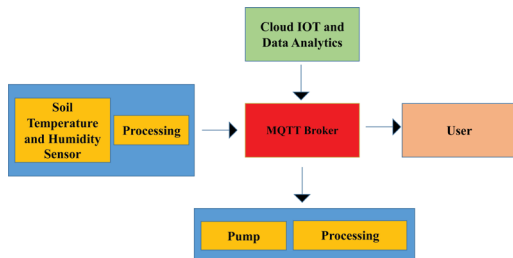
In cases where the sensor fails to provide valid readings, the system logs an error message and retries the data acquisition process. This ensures that transient issues do not disrupt the overall operation of the system. The loop then pauses for a predefined interval (e.g., 1 minute) before continuing, creating a balance between responsiveness and resource efficiency. This smart irrigation system exemplifies the integration of IoT technology in agriculture. By continuously monitoring environmental conditions and making data-driven decisions, it optimizes water usage, ensuring plants receive adequate hydration while minimizing waste. The use of MQTT for data transmission allows for real-time monitoring and control, making the system highly adaptable and scalable for various agricultural applications. This approach not only conserves water but also enhances


Figure 152.2. IoT smart irrigation flow.

crop health and yields, demonstrating the significant benefits of IoT in modern farming practices.

4. Results

To perform the experiments on an MQTT-based smart irrigation system at a minimal level, an affordable microcontroller board such as the Raspberry Pi can be used to collect and process sensor data. Basic sensors for soil moisture, temperature, and humidity will gather essential environmental data. An MQTT broker like Mosquitto, which can run on a low-power computer or cloud service, is necessary for managing data communication. Wi-Fi modules like the ESP8266 will enable the microcontrollers to connect to the network. A cloud-based instance, such as AWS Free Tier, will handle data storage and processing. Cloud storage solutions like Google Drive are needed for data retention. Additionally, simple data analysis and visualization tools will help in understanding and interpreting the collected data, facilitating effective decision-making in irrigation management. To enhance data visualization and analysis, Python libraries such as Matplotlib, Pandas, and Seaborn can be utilized. These tools will provide the means to create clear and informative graphs and charts. By integrating these Python libraries, the system will offer a comprehensive view of the irrigation data, aiding in more accurate and effective management decisions.

Figure 152.3 provides a detailed analysis of how the MQTT-based smart irrigation system handles increasing volumes of sensor data over time. As the number of deployed sensors grows, so does the demand on the system to process data efficiently. By measuring data processing time across various sensor deployment scenarios, this graph illustrates the system's scalability in managing real-time data acquisition and processing. Understanding these variations informs decisions on system architecture, resource allocation, and operational strategies, ensuring optimal performance in dynamic agricultural environments where timely data-driven decisions are crucial.

Figure 152.4 depicts the system's evolving storage space requirements as the number of data points collected from sensors increases. It offers insights into how
the MQTT architecture scales to accommodate growing datasets generated by continuous monitoring of soil conditions and environmental parameters. The visual representation of storage needs against data volume helps in predicting future infrastructure demands, guiding decisions on data retention policies, and optimizing database management practices. This scalability analysis is essential for maintaining data integrity, accessibility, and operational efficiency in smart agriculture applications.

Figure 152.5 showcases the MQTT system's adaptability in optimizing crop yield across different crop types. By comparing percentage improvements in yield achieved through smart irrigation strategies, tailored to specific crop requirements, it demonstrates the system's effectiveness in leveraging real-time data insights and predictive analytics. The visual representation of yield enhancements underscores the system's ability to adapt irrigation schedules, nutrient delivery, and pest management practices to varying crop needs, contributing to sustainable agricultural practices and increased profitability for farmers. This adaptability is crucial for addressing the diverse challenges posed by different crops and environments, ensuring consistent performance and resource optimization in agricultural operations.

In Figure 152.6, the distribution of IoT device deployments across geographic locations is analyzed to assess the MQTT system's adaptability to diverse agricultural environments. By visualizing deployment patterns across regions, the graph highlights the system's capability to maintain robust communication and data transmission capabilities over varying terrains and climatic conditions. Understanding geographic deployment dynamics informs decisions

on network infrastructure expansion, signal strength optimization, and redundancy planning, ensuring reliable connectivity and operational continuity across expansive agricultural landscapes. This adaptability test validates the system's resilience and scalability in supporting precision agriculture initiatives, enabling farmers to monitor and manage their fields effectively while maximizing resource efficiency and crop yields.

5. Conclusion and Future Work

The implementation of an IoT-based smart irrigation system showcased in this study marks a significant advancement in agricultural water management. By utilizing real-time data from soil sensors via MQTT and cloud-based analytics, the system achieves precise and efficient irrigation. Automated controls optimize water usage by activating irrigation based on moisture thresholds, reducing waste and enhancing crop yield. This approach underscores IoT's transformative impact on agriculture, promoting sustainability and resource efficiency. The system efficiently handles increasing sensor data, informing scalable architecture decisions and optimizing database storage. Its adaptability is demonstrated through tailored irrigation strategies that optimize crop yields across different types. In diverse geographic deployments, the system ensures reliable connectivity, supporting precision agriculture effectively. Future work includes enhancing predictive analytics capabilities and integrating more advanced machine learning models for even more precise irrigation scheduling. These advancements aim to further reduce water consumption while maximizing agricultural productivity, reinforcing MQTT's pivotal role in sustainable farming practices.

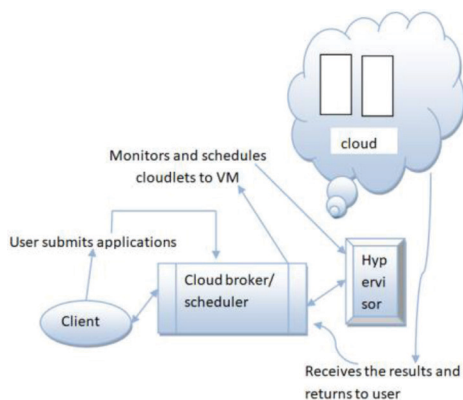
Abstract: Cloud computing meets the technological needs of businesses and supports a variety of other technologies. In addition, the emergence of advanced technologies has led to a significant rise in the requirement for processing power and storage capacity. Blockchain and large-scale data storage will function better as a result of advancements in the use of cloud computing, which underpins both technologies. A critical strategy to take into account while taking into account the needs of exceptional computing power is the intelligent allocation of cloud resources. This work presents the effective allocation of resources technique (FTVMA), which comprises the creation of efficient virtual machines (VMs) and maximizing the effectiveness of VM allocation by considering failure rates, the historical failure history of VMs, and executing effectiveness as an important aspect of effective scheduling. Numerous things can lead to VM cloudlet malfunction. Virtual machine overflow and unavailability are a couple of these. The introduced FTVMA algorithm considers the failure rate of the actual system, the load of simulated machines, and the cost-priority of the jobs in order to accomplish the Quality of Service (QoS) and Quality of Environment (QoE) of the user. The FTVMA methodology, more efficient for computing-intensive virtual machines (VMs), is tested in the Cloud Sim environment. The efficacy of the proposed approach is assessed using QoS metrics, namely span and VM Utilization. The priority missed rate and the failure rate are the two metrics used to quantify QoE. The QoS and QoE metrics show how much the recommended strategy has improved. The proposed technique outperforms the existing resource scheduling methods with regard to of QoS and QoE, according to the comparison of the results.

Keywords: Cloud computing, scheduling, load balancing, fault tolerance, virtual machine allocation

1. Introduction

These days, a lot of other methods, like deep learning, cryptography, big data, and cloud computing, employ this developing computing technique when processing vast amounts of data is required. Nonetheless, a significant amount of data is kept in the cloud, and it is probably safe. In essence, resource suppliers are in charge of both the data safety and the efficient use of these resources. "Cloud computing" is defined as "a model for permitting ubiquitous, convenient, on-demand system access to a collective collection of configurable computing assets (e.g., networks, storage devices, servers, apps, and services) that are capable of being quickly provisioned and distributed with minimal effort from management or supplier interaction" by the National Institute of Standards and Technology [1]. In order to provide cloud computing services, a number of computing service suppliers, such as Google, Microsoft, Yahoo, and IBM, are quickly building data

centers in different parts of the world [2]. The practice of bringing up an archive of data kept in one cloud to a separate one is known as cloud-to-cloud backup, and it is now popular in the cloud computing industry. User satisfaction in cloud environments requires focus on a number of areas, including migration, consolidation, and scheduling of virtual machines. Numerous cloud computing infrastructures are made up of dependable services that are provided by information centers. A platform made up of potentially enormous quantities of consumers from various contexts, each with varied wants and requests, and tens of millions of virtual machines awaiting their time to be serviced is the definition of this NP hard issue [7, 9]. Every provider of cloud services wants to make sure that each asset is used to its utmost potential in order to prevent resources from being idle [10]. Therefore, use of resources is regarded as a crucial factor in determining how well a scheduling system performs.

Figure 153.1 depicts the fundamental cloud scheduling architectural design. The design employs a method whereby users send their jobs to the cloud broker. Work is divided into smaller tasks. Another name for the cloud facilitate is a cloud scheduler. The job tracking and scheduling functions of the cloud scheduler aid in the selection of virtual machines (VMs) for the provided cloudlets. The Hypervisor, which manages the VMs, provides the cloud scheduler with data on the accessible VMs. A suitable virtual machine is chosen for each cloudlet. The VM is allotted the cloudlets, and the intermediary receives its findings back. This scheduling process must be carried out efficiently so that time spent on tasks are kept to a minimum. Researchers from all over the world have put out a number of research projects to create a productive and effective scheduling method. This research aims to provide a proactive, fault-tolerant scheduling system that minimizes execution time and boosts customer happiness.


2. Literature Review

Groups are formed to split the duties and minimize the amount of unwanted communication. The goal of the effective resource provision solutions that are suggested [2] is to scale cloud resources simultaneously lowering power usage. This approach focuses on estimating the proper quantity of assets that have to be provided and accurately predicting the processing demands of a distributed server. Both the expense of construction and energy usage are decreased by this approach. A cloudlet with the largest complete time and a cloudlet containing the least completion time are identified by the MMax-Min algorithm. The VM is assigned to the cloudlet of choice according on the work requirements, including cost and deadline. In regard to duration and load distribution, the algorithm's efficiency corresponds to that of the Max-Min and Round Robinal algorithms. An efficient scheduling method that takes priority scheduling into account and lowers the total time to execute of all cloudlets is the Extended Min-Min algorithm [6]. As a mediator among the cloud customer and supplier, this algorithm receives, evaluates, and distributes the program to the relevant and obtainable assets. This approach seeks to improve the cloud use of resources ratio while shortening the production span.

As specified by the person using it. In [13], a work algorithm for scheduling called LGSA—a combination of the lion optimisation method—is developed. This algorithm attempts to tackle the issue of scheduling for optimization with multiple goals. The issues of utilization of resources, cost, energy, and virtual machine overcrowding and underloading are dealt with.

Compared to other heuristic algorithms, the classic Min-Min algorithm minimizes span and is an effective yet straightforward algorithm. The largest flaw in it is the uneven distribution of resources. It is suggested to use an enhanced load-balanced minimum algorithm [14] to maximize the use of resources. In order to

Figure 153.1. Basic cloud scheduling architecture.

improve user happiness, the user's preference for the tasks is also taken into consideration.

Scheduling using the BAT algorithm is covered in [17]. The BAT method is an optimisation method that uses a self-learning improvement calculation in its computation. The concept of the bats' natural arrangement is used in the computation. Typically, bats send pulses of ultrasonic sound into their surroundings. The ultrasonic pulses that are released will reverberate as echo. The bat detects obstacles and potential prey by capturing the echoes it produces and using the echoes it receives. This idea might be used to schedule issues and identify the best solution. Suggested algorithm for multi-constrained planning [4] takes into account many constraints, including system load, process cost, time for processing, user's deadline, and resources failure. An algorithm for allocating resources is created that is both user-satisfied and resistant to failure, while adhering to strict budget and load constraints. Based on fault tolerance the article discusses a load rebalancing scheduling system [16] that addresses either failure tolerance and balanced load. A proactively fault tolerance technique is presented, whereby the disparity factor is calculated according to the consumer's deadlines and the projected time of accomplishment. The primary tool for choosing the best resource is the calculated Resource Choice Parameter.

For IaaS clouds, an intuitive load balancing mechanism is suggested in [15]. In order to achieve the highest utilization rate of the computational resource, an effective approach is established that establishes the servers depending on the quantity and sizes of duties submitted, finds the appropriate virtual machines (VMs), and allocates the assignments to the workers.

2.1. Problem statement

The three issues of minimizing (1) the time taken to complete all tasks provided; (2) increasing resource consumption; and (3) reducing the percentage of failed of supplied cloudlets are addressed by distributing the cloudlets to the accessible virtual machines (VMs). We call this scheduling that is fault-tolerant. Assume that the cloud service operator has virtual machines (VMs) accessible, and that there are cloudlets. The properties of the cloudlets have been established, such as cloudlet length and cloudlet_Id. The virtual machines are defined by attributes such as VM_Id, VM_speed, VM_workload, and VM_availability. Every Physical Machine (PM) has a set amount of virtual machines (VMs) allocated to it.

2.2. Cloud scheduling model

The cloudlet schedule model, together with its attributes, is presented in Figure 153.2. This design explains the cloudlet, virtual machine, and efficiency metrics in detail.

The task of matching apps that take the format of cloudlets with the resources needed to run them in the form of virtual machines (VMs) is carried out by the scheduler. The scheduling tool can fully examine the properties of programs before they are executed, as well as the properties of the computing facilities that are accessible, and it may offer users the appropriate resources for their software applications.

3. Proposed Model

Figure 153.3 illustrates the scheduling structure that the suggested FTVMA algorithm adheres to the user sends the apps to the cloud broker. Receiving the apps and dividing them up into cloudlets is the responsibility of the cloud broker. The roles of a cloud broker include scheduler, fail detector, load predictor, the cloudlet monitor, and virtual machine monitor. The VM Monitor is in charge of keeping an eye on the load, accessibility, quantity of submitted, finished successfully, and failed-to-execute cloudlets as well as the list of cloudlets currently queued up.

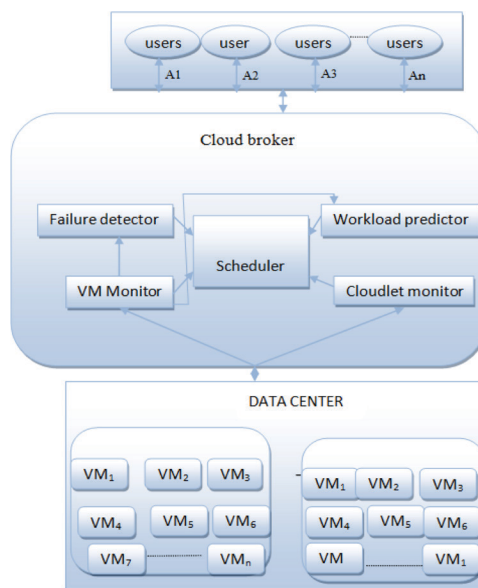
The task of keeping an eye on the cloudlet's size and complete status falls to Cloudlet Monitoring. The total amount of clouds uploaded when they're finished is reported to the Failure Detector, which then computes the error rate for every virtual machine. The Workload Predictor obtains data from the VM Track to forecast the present load of the virtual machine. Using all of this data, the Scheduler finds the right virtual machine


Figure 153.3. Proposed FTVMA scheduling architecture.

Source: Author.

(VM) for every cloudlet. The virtual machines (VMs) built in this scheduling modelling have attributes like speed, inability rate, prepared time, and work load. It is possible to determine a process's velocity or capability as:

$$S_j = MIPS_j \qquad (1)$$

The quantity of clouds accepted to VMj is provided by CLjsub. The quantity of clouds that the VM_j successfully finished is reported by CLjsucc, and the quantity of cloudlets, which are that the CL jf gave as a failure. The VMj rate of failure may be computed.

$$FR_j = \frac{CL_{if}}{CL_{jsub}} \qquad (2)$$

The "ready time" VMj is the point in time when the virtual machine (VM) completes the cloudlets that have already been assigned and is available to run the current. This is specified by:

$$LCT_j = \sum_{k=1}^{p} ETE_{jk} \qquad (3)$$

The total amount of cloudlets assigned to VMj and ETEj, which represents the anticipated time spent running the cloudlets in VMj, together determines the work load of VMj.

$$WLD_j = \sqrt{\sum_{k=1}^{p} a_k L_k^2} \qquad (4)$$

Wherever LK the virtual machine's load property is the load characteristic in this FTVMA method takes into account the CPU use in seconds. From now on, the load may be assigned as:

$$WLD_j = \frac{\sum_{j=1}^{n} Ml_j}{S_j X AT_j} \qquad (5)$$

Now the new load of VMj is given as:

$$NLD_j = WLD_j + \frac{Ml_j}{S_j X AT_j} \qquad (6)$$

Then the expected time for execution is given by:

$$ETE_{i,j} = \frac{size(CL_i)}{speed\ (VM_j)} \qquad (7)$$

The quantity of cloudlets that are effectively finished as a Hit Count is determined by:

$$HC_{tot} = \sum_{j=1}^{M} HC_j \qquad (8)$$

Here is every single VM's hit count that is computed as:

$$HC_j = \frac{CL_{jsucc}}{CL_{jsub}} \qquad (9)$$

The FTVMA method is used by the scheduling of the Cloud Sim technology. The technique's notations including the FTVMA Scheduling technique is shown in algorithm.

1. Receiving the submitted cloud lets CLi from user area side using cloudlet monitoring
2. Collecting the available information of VM's like workload WLj, speed Sj, failure rate FRj and availability time ATj using VM monitoring
3. $\forall CL_i \in \{CL_1, CL_2, CL_3, \ldots \ldots CL_n\}$
   $\forall VM_j \in \{VM_1, VM_2, VM_3, \ldots \ldots VM_m\}$
   do
   Now calculating the expected time for executing the following
   $ETE_{i,j} = \frac{Ml_j}{S_j}$
   here S_j is the processing speed VM$_j$ is instrucions per second in million ML$_i$ representingthe size of CL$_i$ in millian instructions
   Calculating the total time for execution TT$_{i,j}$ using equation as given
   TT$_{i,j}$ = ETE$_{i,j}$ + LCT$_j$
   end
5. $\forall CL_i \in \{CL_1, CL_2, CL_3, \ldots \ldots CL_n\}$
   Do sort the VM's in ascending order based on there TT$_{i,j}$
   Sort the VM's in ascending order based on there FRj
   Now select the first VM from the sorted list and assign the corresponding cloudlet
   $\forall CL_i$ except allotedLCT$_j$ update TT$_{i,j}$ of the selected VM$_j$
   updateLCT$_j$ and WLD$_j$ upon each allocation
   end
6. Calculate make span of the schedule using the formula
   Makespan = max{LCT$_j$}
7. calculate the utilization of VM as
   $VM_{util} = \frac{\sum_{j=1}^{n} Ml_j}{S_j X AT_j} X\ 100$
8. calculated average utilization is specified by,
   $AV_{util} = \frac{1}{N} \sum_{j=1}^{N} VM_{util_j}$
9. calculate the HIt count as
   $HC_{tot} = \sum_{j=1}^{M} HC_j$

4. Results and Discussion

The main goal of the suggested FTVMA algorithm is to minimize the makespan. A active, fault-tolerant method that evaluates the likelihood of failure at the point of scheduling is presented. The cloud simulator is used to evaluate the FTVMA, and the outcomes are compared to algorithms for scheduling that are currently in use, such as Min-min, LBIMM method [14], and EMin-Min method [6].

Through the application of mathematical equations to calculate and analyze the interactions between the system's many elements, or by physically capturing observation through a manufacturing facility, computer programs are employed to model the actions of systems (CPUs, networks, etc.) [18]. A framework called Cloudsim was created by the University of Melbourne's GRIDS Group to facilitate continuous simulation, simulation, and experimentation with cloud computing network architecture [18]. The suggested method's performance is assessed using the Cloudsim simulation environment. The traits and attributes of clouds that are relevant to this work are covered below. The cloud-sim structure depicted in Figure 153.4 consists of a data the center, a scheduler that implements the suggested scheduling method, cloudlets, virtual machines, and an actual host.

A large-scale cloud platform's the host, servers, service brokers, organizing, and assignment policies may all be modelled using Cloudsim [19]. Cloud aids in virtual machine deployment on two distinct levels: both at the host and virtual machine levels. You can set the percentage of every core's total processing power that will go toward each virtual machine (VM) at the host level. Each cloudlet is assigned a fixed amount of processing power by the virtual machine (VM). We call this VM Scheduling [19]. All data centers ought to register on the Cloud Data Service Registration (CIS). Appropriate providers of cloud services are mapped to the individual's requests. The CIS publishes the list of cloud providers that are accessible. The list's providers of cloud computing who can offer the required services are selected, and the program is filed with the ideal match [18–25]. The key elements of Cloudsim and their connections are listed below.

Host: It represents a real server.

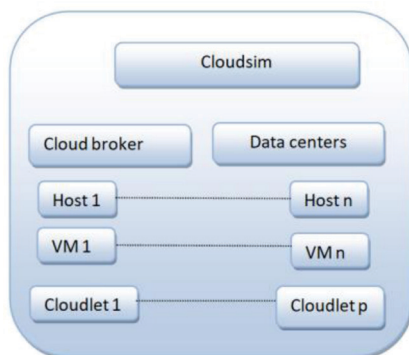
VM: It simulates a host-based virtual machine. The cloud-based services for applications are modelled by Cloudlet. The data center: It represents services that the cloud service providers offer. Compute hosts might be heterogeneity or homogeneous. CIS: An organization that registers as a data center and locates the source.


Figure 153.4. Cloudsim architecture.

Source: Author.

VM Allocation: A data center-level supplying policy. It assists with VM host allocation.

VM Scheduler: Remotely assigns processors to virtual machines.

The Cloudlet Scheduler provides strategies to distribute processing power across the cloudlets within a virtual machine (VM) [19].

In this experiment, 512 cloudlets and 16 virtual machines were built. The cloudlet's defined properties are displayed in Table 153.1.

The properties of the VMs specified by the simulation are shown in Table 153.2.

4.1. Performance metrics

The suggested FTVMA algorithm is assessed using makespan, hit count, and average VM utilization as indicators of performance. These metrics unambiguously characterize efficiency in an approach that guarantees the level of QoS (makespan and hit count) and the level of QoE (average VM utilization). These metrics have definitions below.

Makespan: It's the most ready time to exit the virtual machines. Every possible virtual machine's LCT is computed, and the greatest number of all LCTs is referred to as makespan and is determined by a calculation.

$$makespan = \max\{LCT_j\} \tag{10}$$

HitCount is described as the total amount of cloudlets that have been uploaded for that schedule and that were executed effectively, with no any failures. Each virtual machine's hit count is determined utilizing equation (9) and the total hit count is determined utilizing equation (8).

VM Utilization on average: Equation (11) provides the calculation for every virtual machine's efficiency

Table 153.1. Characteristics of cloud let

Characteristics	Range

based on the load that is given to it through the scheduler.

$$VM_{util} = \frac{\sum_{j=1}^{n} Ml_j}{S_j X AT_j} X \ 100 \qquad (11)$$

and the equation (12) yields the Average VM Efficiency.

$$AV_{util} = \frac{1}{N} \sum_{j=1}^{N} VM_{util_j} \qquad (12)$$

4.2. Experimental results

The suggested FTVMA algorithm is assessed in the experimental configuration described previously, and the outcomes are contrasted to those of the currently in use algorithms, Min-min, LBIMM, and EMin-Min [14, 6] he assessment data sets are divided into four distinct situations, each containing 16 virtual machines and 512 cloudlets. The data in:

Case 1 is represented by cloudlets and virtual machines that operate using lower performance requirements (LVLC).

Case 2 shows data comprising massive cloudlets and high-performing virtual machines (VMs) that need high-performance resources to run (HVHC).

Case 3 shows the data with large clouds and low-performing virtual machines (VMs) that demand high-performance resources to run (LVHC).

Case 4 shows the data with high-performing cloudlets and virtual machines that need low-performance resources to run (HVLC).

The data are organized under these four situations while the many combinations that were taken reflect all kinds of real-time occurrences. Figure 153.5 shows the effectiveness analysis of FTVMA determined by makespan. According to the results, the suggested FTVMA has a shorter make-span than the Min-min, EMin-min, and LBIMM methods that are already in use. TVMA minimizes the makespan by allocating virtual machines according to failure rate and minimal time to execute.

Therefore, compared to previous methods, the suggested algorithm has a comparatively smaller makespan. Data taken into consideration in Case 4 is the low-requirement cloudlet and high-performing virtual machine. Therefore, the makespan of all the methods has significantly decreased.
Figure 153.5. FTVMA performance evaluation according to milliseconds of makespan.

Source: Author.

The hit count is a crucial parameter for assessing effectiveness according to failure rate. When comparing hit_count, the suggested FTVMA displays a greater quantity of completed channels with no errors. The contrast is shown in Figure 153.6 and demonstrates that, because the LBIMM isn't focused on VM failing rate, it has a lower hit count compared the other algorithms. While contrasted with the alternative algorithms, the suggested FTVMA method has a higher hit count.

The average virtual machine (VM) usage is an indicator of performance metric for the purpose of VM usage. Figure 153.7 compares the four scenarios and suggests that, on average, the suggested FTVMA method has enhanced VM usage by 89%. The VM utilization appears to be exhibiting a comparable spectrum of values in percentage across scenarios.

5. Conclusion

This paper presents a fault-tolerant oriented scheduling technique that minimizes the makespan and provides an ideal match among virtual machines (VMs) while accounting for their failure likelihood. The proposed algorithm is tested in three different scenarios: efficient virtual machines (VMs) receive low requirement cloudlets, low performing VMs receive low demand cloudlets, and low performing VMs receive extremely needed cloudlets. In our real-time cloud environment,
Figure 153.6. According to the hit count, an assessment of FTVMA's productivity.

Source: Author.
Figure 153.7. Evaluation of FTVMA's effectiveness according to average VM usage.

Source: Author.

these four categories must be addressed. By considering all of these factors, the proposed FTVMA approach optimizes VM consumption, boosts hit count, and decreases makespan. This work can be extended to consider under loaded and overburdened virtual machines, thereby accounting for other parameters like scalability. This might be taken even further by using approaches for dynamic virtual machine aggregation.

154 Design and implementation of a sensor-integrated IOT system for enhanced crop monitoring and management

Palvi Soni[1,a] and Gajendra Tandan[2,b]

[1]Assistant Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: Crop monitoring plays a crucial role in optimizing resource utilization and promoting sustainable agricultural practices through continuous assessment of environmental factors. By leveraging sensors such as the DHT11 for temperature and humidity, BMP180 for atmospheric pressure, SEN0114 for soil moisture, and MQ135 for air quality, farmers can gather real-time data essential for precise agricultural management. This integrated IOT-based system begins with sensor deployment across the field, ensuring comprehensive coverage for monitoring crop health parameters. Data collected from these sensors is transmitted to a central Raspberry Pi unit, where it undergoes pre-processing to ensure accuracy and consistency. The pre-processed data is then securely transferred to the Kaa IoT platform, which serves as the backbone for data storage, real-time monitoring, and advanced analytics. Through intuitive interfaces provided by the Kaa platform, farmers gain actionable insights into environmental conditions, enabling informed decision-making on irrigation scheduling, fertilizer application, pest management, and environmental control measures. Results obtained from temperature trends inform adjustments in planting and harvesting schedules to maximize crop growth potential, while humidity levels guide precise irrigation practices to maintain optimal moisture levels without exposing plants to risks of disease or stress. Soil moisture data facilitates efficient water management, minimizing runoff and conserving water resources. Additionally, monitoring atmospheric pressure provides early warnings of weather changes, allowing proactive measures to protect crops from adverse conditions. By integrating these data-driven insights into agricultural practices, farmers can optimize resource utilization, reduce environmental impact, and enhance overall crop resilience and productivity.

Keywords: Crop monitoring, temperature, humidity, atmospheric pressure, soil moisture, raspberry Pi, Kaa IoT platform, water management

1. Introduction

Crop monitoring is undeniably crucial for modern agriculture, playing a pivotal role in ensuring optimal yields, sustainable farming practices, and food security. At its core, crop monitoring involves the systematic observation and assessment of crops throughout their growth cycle. This process allows farmers to gather essential data on various factors such as crop health, growth stages, pest infestations, and environmental conditions [19]. One of the primary benefits of crop monitoring lies in its ability to detect early signs of stress or disease in crops [1]. In the context of climate change, crop monitoring becomes even more critical [4]. In essence, crop monitoring is not just about observing fields; it is about harnessing data-driven insights to optimize agricultural practices. As global food demand continues to rise, the role of effective crop monitoring will only become more crucial in ensuring food security and sustainable agricultural development worldwide [6]. By monitoring soil moisture, nutrient levels, and crop growth stages, farmers can optimize irrigation schedules and tailor fertilizer applications accordingly. Furthermore, in the face of climate change, crop monitoring becomes crucial for enhancing resilience. By monitoring weather patterns and soil conditions, farmers can adapt cultivation practices to mitigate risks from extreme weather events and shifting climate conditions [11].

2. Literature Review

Before the era of modern agricultural technology, crop monitoring primarily relied on several traditional methods, each with its own set of advantages and limitations. These methods were essential for farmers and agricultural experts to assess crop health, predict yields, and make informed decisions about management practices. Visual inspection and field surveys involved direct observation of crops by walking through fields or from vantage points nearby. Farmers and agronomists would visually assess crop growth stages, detect signs of pest infestations, disease outbreaks, and nutrient deficiencies [12]. This method provided first-hand insights into crop conditions and allowed for immediate identification of problems. However, its effectiveness heavily relied on the observer's experience, as detecting subtle variations in crop health or pest damage required a trained eye. Moreover, visual inspection was limited by its inability to cover large areas comprehensively within a short period [13]. As a result, it was time-consuming and sometimes impractical for extensive farming operations.

Weather monitoring played a crucial role in crop monitoring before advanced technology [18]. Farmers would track rainfall patterns, temperature fluctuations, and humidity levels using basic meteorological instruments such as rain gauges and thermometers [14]. These observations helped predict crop growth stages (phenology) and plan planting and harvesting schedules accordingly. For instance, the appearance of specific plant growth stages (like flowering or fruiting) in relation to accumulated degree days or day length could guide farmers in making decisions about irrigation, fertilization, and pest management [15]. However, weather monitoring was limited by the availability of accurate and timely data. Local weather stations were sparse in many regions, and data collection was often manual and prone to errors. Additionally, weather patterns could vary significantly across different parts of a farm, making localized decision-making challenging.

Soil sampling and analysis were crucial for assessing soil fertility, nutrient levels, pH balance, and salinity factors critical for crop growth and health [16]. Farmers and agronomists would collect soil samples from various points in the field and send them to laboratories for analysis in Table 154.1. This process helped determine the need for fertilizers and soil amendments, enabling targeted and efficient nutrient management [17]. However, soil analysis was limited by the time it took to collect samples, send them for analysis, and receive results. It also required knowledge of sampling techniques to ensure representative samples were obtained. Moreover, the results were static and provided only a snapshot of soil conditions at the time of sampling, without real-time feedback on soil dynamics during the growing season.

3. Proposed Work

Integrating various sensors such as the DHT11 for temperature and humidity, BMP180 for atmospheric pressure, SEN0114 for soil moisture, and MQ135 for air quality plays a pivotal role in ensuring optimal crop health and maximizing yield. The DHT11 sensor provides accurate readings of temperature and humidity, which are crucial for understanding the microclimate around the crops. Temperature and humidity directly influence plant growth, photosynthesis rates, and the potential for disease outbreaks. By monitoring these parameters, farmers can take timely actions to create optimal growing conditions, such as adjusting greenhouse ventilation or activating irrigation systems to maintain ideal humidity levels. The BMP180 pressure sensor adds valuable data about atmospheric pressure, which is essential for weather forecasting and understanding climate patterns. Changes in atmospheric pressure can indicate impending weather changes, allowing farmers to take proactive measures to protect their crops from extreme weather conditions, such as storms or frost. This sensor helps in planning agricultural activities, ensuring they are carried out during favorable weather conditions to minimize crop stress and damage.

Soil moisture is another critical factor in crop health, and the SEN0114 soil moisture sensor provides real-time data on the water content in the soil. Proper soil moisture management is vital for plant health, as both overwatering and underwatering can lead to poor crop performance and yield. By using the SEN0114 sensor, farmers can optimize irrigation schedules, ensuring that crops receive the right amount of water at the right time

Table 154.1. Sensors used in crop monitoring

Sensors	Model
Temperature	DHT11
Humidity	DHT11
Soil moisture	SEN0114
Pressure	BMP180
Air quality	MQ135

Source: Author.

in Figure 154.1. This not only enhances plant growth but also conserves water resources and reduces the risk of waterlogging or drought stress. Air quality is a significant factor that can affect crop health, and the MQ135 sensor measures the concentration of various gases and pollutants in the air. Poor air quality, resulting from high levels of harmful gases like ammonia, nitrogen oxides, and volatile organic compounds, can negatively impact crop growth and yield. The MQ135 sensor helps farmers monitor air quality and take necessary actions, such as adjusting ventilation systems or using air purifiers, to ensure that crops are growing in a clean and healthy environment.

The process begins with the deployment of various sensors throughout the agricultural field to gather essential data such as soil moisture, temperature, humidity, and light intensity. These sensors, which include soil moisture sensors, temperature sensors, humidity sensors, and light sensors, are strategically placed to ensure comprehensive coverage of the field. Each sensor is connected to a central processing unit, typically a Raspberry Pi, known for its versatility and cost-effectiveness in IoT projects. The Raspberry Pi, which is connected to a stable power source like a battery pack or a direct electrical connection, acts as the brain of the system. Once powered, it runs a Python script specifically designed to interface with the sensors and collect data at regular intervals. This script uses libraries like GPIO for sensor communication and pandas for data handling, allowing the Raspberry Pi to gather data from the sensors via its GPIO (General Purpose Input/Output) pins or through a connected sensor network using protocols such as I2C, SPI, or UART.

As the data is collected, the Python script preprocesses it by cleaning and formatting it, ensuring it is suitable for further analysis and transmission. This preprocessed data is then sent to the Kaa platform, an open-source IoT platform that provides robust services for data management, real-time monitoring, and device management. The Kaa platform facilitates the secure storage and processing of data, making it accessible to users through a web interface or a mobile application. Through the Kaa platform, users can receive real-time updates and detailed information about their crops, displayed through intuitive dashboards and visualizations. They can set alerts for specific conditions, such as low soil moisture or high temperature, which are crucial for making timely decisions regarding irrigation, fertilization, and other agricultural practices. Additionally, the platform employs machine learning algorithms to offer predictive analytics, providing insights into future crop conditions based on historical data.

Remote users interact with the IOT platform through various interfaces, enabling them to monitor and control the IOT devices from anywhere in
Figure 154.2. IOT architecture of the proposed system.

Source: Author.

the world. These users might include farmers monitoring crop conditions, factory managers overseeing industrial equipment, or homeowners managing smart home devices. The IOT platform provides them with real-time alerts, reports, and control mechanisms, empowering them to make informed decisions and take prompt actions in Figure 154.2. Secure authentication and access control mechanisms ensure that only authorized users can access the system, protecting sensitive data and preventing unauthorized manipulation of devices. The IOT platform in the cloud provides a comprehensive suite of tools for device management, data analytics, and application development. It enables remote users to access and interact with the IOT system through user-friendly interfaces, such as web dashboards and mobile apps.

The platform supports device provisioning, firmware updates, and configuration management, ensuring that devices remain operational and secure. It also offers data visualization tools that help users interpret the data and gain actionable insights. The platform's analytics capabilities allow for real-time monitoring, predictive maintenance, and anomaly detection, enhancing the overall efficiency and reliability of the IOT system. The IOT gateway serves as a bridge between the IoT devices and the cloud infrastructure. It aggregates data from multiple devices, performs preliminary processing, and ensures secure data transmission to the cloud servers. The gateway is responsible for handling communication protocols, managing network traffic, and providing a secure channel for data transfer. It may also perform edge computing tasks, processing data locally to reduce latency and bandwidth usage. The gateway ensures that only relevant and processed data is sent to the cloud, optimizing resource usage.

4. Results

The system requirements for a crop monitoring include a network of sensors such as the DHT11 for temperature and humidity, SEN0114 for soil moisture, BMP180 for pressure, and MQ135 for air quality.

These sensors integrate with the Kaa IoT platform for data aggregation and management. Python-based scripts are utilized for real-time data visualization and analysis, leveraging libraries like Matplotlib and Plotly for creating graphs and charts. This setup facilitates comprehensive monitoring of environmental conditions crucial for crop growth. By visualizing sensor data through Python, stakeholders can gain actionable insights to optimize irrigation, fertilization, and pest control strategies, ultimately enhancing agricultural productivity and sustainability.

Figure 154.3 provides a detailed visual representation of how temperature changes over the course of a day, measured in degrees Celsius. The x-axis displays rounded hourly timestamps (e.g., 4:00, 5:00, 6:00) without specific dates, offering a focused view on hourly temperature trends. Each data point, marked by blue circles and connected by a continuous line, signifies a temperature reading recorded at that specific hour. This graphical presentation enables a comprehensive examination of temperature fluctuations throughout the day, allowing for insights into daily temperature patterns that are critical for optimizing agricultural practices. Farmers and agronomists can use this information to make informed decisions regarding irrigation timing, crop selection, and management strategies aimed at maximizing crop health and yield under varying temperature conditions.

Figure 154.4 visualizes humidity trends over time, crucial for crop monitoring to ensure optimal growth conditions. By plotting humidity (%) against time (in hours), the graph provides insights into how humidity fluctuates throughout the day. This information is vital for farmers and agronomists as it directly impacts crop health and growth. The x-axis displays time in hourly intervals, starting from 8:00 AM to 1:00 PM, with each data point representing the average humidity recorded at that hour. This granularity helps identify patterns such as peak humidity levels or fluctuations during specific times of day. The y-axis measures humidity percentage, indicating the moisture content in the air. This metric is pivotal for assessing plant transpiration rates, disease susceptibility, and overall crop stress levels. For instance, a steady decline in humidity from morning to noon might suggest increasing water demand from plants as temperatures rise. The markers ('o') on the line plot highlight actual data points, enhancing clarity on specific humidity readings at distinct hours. The green line connects these points, illustrating the overall trend across the morning hours.

Figure 154.5 instrumental in crop monitoring as it illustrates the dynamic relationship between soil moisture levels and time throughout the day. By plotting soil moisture percentage against hourly timestamps, the graph offers valuable insights into the soil's water content variations crucial for agricultural management. Farmers can interpret the data to determine

Figure 154.5. Soil moisture vs time.

Figure 154.6. Air quality index vs time.

Source: Author.

optimal irrigation schedules, ensuring crops receive adequate water without overwatering, which can lead to root diseases or nutrient leaching. For instance, a gradual decline in soil moisture throughout the morning might indicate increasing water demand from crops as temperatures rise. Conversely, sudden spikes or dips in moisture levels could signal irrigation inefficiencies or unexpected weather impacts. This visual representation enables timely adjustments in irrigation practices, enhancing crop health, yield, and resource efficiency. Overall, the graph serves as a practical tool for farmers to make informed decisions based on real-time soil moisture data, ultimately optimizing agricultural productivity and sustainability.

Figure 154.6 depicting air quality index (AQI) and atmospheric pressure over time are essential tools in modern crop monitoring and management practices. The AQI graph provides a detailed view of how pollutant levels fluctuate throughout the day, offering critical insights into environmental conditions that directly impact crop health. Farmers can use this information to assess potential risks posed by air pollutants such as ozone, nitrogen dioxide, and particulate matter, which can affect photosynthesis, nutrient uptake, and overall plant growth. By tracking AQI trends alongside crop growth stages, agricultural practitioners can make informed decisions on irrigation timing, pest and disease management, and air quality interventions to optimize yield and quality.

Figure 154.7 tracks changes in barometric pressure, a key indicator of imminent weather changes. Fluctuations in pressure influence temperature, humidity levels, and precipitation patterns, all of which profoundly impact crop development and yield. By monitoring these trends, farmers can anticipate weather fronts, adjust planting and harvesting schedules accordingly, and implement protective measures to mitigate potential crop damage from adverse weather conditions such as storms, frost, or drought. This proactive approach

not only enhances resilience against environmental variability but also supports sustainable agricultural practices by optimizing resource use and minimizing environmental impacts. Together, these graphical representations empower farmers with actionable insights to adapt swiftly to changing environmental conditions, ultimately ensuring efficient crop management and sustainable agricultural productivity.

5. Conclusion and Future Work

The integrated IoT-based agricultural monitoring system begins with sensor deployment DHT11 for temperature, BMP180 for pressure, SEN0114 for soil moisture, and MQ135 for air quality. Data undergoes pre-processing on a Raspberry Pi before securely transferring to the Kaa IoT platform. As a result, farmers gain insights for informed decision-making on irrigation, pest management, and environmental control, enhancing crop yield and sustainability. Temperature and humidity inform planting schedules, while soil moisture and AQI guide irrigation and air quality interventions. Future work includes pH and spectral sensors for comprehensive monitoring, advanced analytics with machine learning for disease detection, and integration of satellite imagery for precise management. Addressing scalability and interoperability will optimize resource use and ensure sustainable agricultural practices, vital for maximizing yield and environmental stewardship in modern farming.

155 Integrating machine learning and data lakes for improving predictive maintenance and industrial IoT applications

Nidhi Mishra[1,a] and Ghorpade Bipin Shivaji[2,b]

[1]Assistant Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: In today's industrial landscape, the integration of machine learning with advanced data management solutions such as data lakes is reshaping predictive maintenance and Industrial IoT applications. This abstract explores the transformative potential of combining these technologies, focusing on Databricks Lakehouse, Azure IoT Edge, data normalization, Deep Q-Networks, ARIMA (AutoRegressive Integrated Moving Average), CoAP (Constrained Application Protocol), and Convolutional Neural Networks. ML algorithms, including ARIMA for time-series forecasting and CNNs for anomaly detection, are pivotal in analyzing sensor data to predict maintenance needs accurately. Databricks Lakehouse serves as a centralized repository, accommodating diverse data types and facilitating advanced analytics. Azure IoT Edge enhances real-time data processing capabilities, enabling immediate responses to insights derived from the data lakes. Data normalization ensures consistent and reliable analysis across varied datasets, enhancing the accuracy of ML models. CoAP supports efficient communication between IoT devices and data lakes, crucial for seamless data transmission in IIoT environments. CNNs excel in spatial data processing, detecting anomalies and patterns critical for proactive maintenance. However, challenges include data integration complexities, scalability issues, and security concerns, necessitating robust solutions. The integration of ML and data lakes offers immense potential for enhancing predictive maintenance and IIoT applications.

Keywords: Databricks lakehouse, Azure IoT edge, data normalization, deep Q-Networks (DQN), ARIMA (AutoRegressive integrated moving average), CoAP (constrained application protocol), convolutional neural networks (CNN)

1. Introduction

In recent years, the convergence of machine learning techniques and advanced data management solutions like data lakes has revolutionized industrial operations, particularly in the realm of predictive maintenance and IIoT applications [1]. This introduction explores the transformative potential of integrating machine learning with data lakes, focusing on how technologies such as Databricks Lakehouse, Azure IoT Edge, data normalization, DQN, ARIMA, CoAP and CNN are reshaping the landscape of industrial efficiency and reliability. By leveraging patterns and anomalies in this data, machine learning models can predict equipment failures before they occur, thereby enabling proactive maintenance strategies that minimize downtime and optimize operational efficiency. However, the effectiveness of these models hinges on the quality, volume, and accessibility of the data they analyze. This capability allows for comprehensive data aggregation, facilitating advanced analytics and machine learning model training without the constraints of predefined schema or data silos [5]. Azure IoT Edge extends this capability by enabling real-time data processing and analysis at the edge of the network, closer to where data is generated [6]. Combined with data lakes, Azure IoT Edge empowers industrial enterprises to leverage timely insights for immediate decision-making and adaptive maintenance

strategies [8]. This process enhances the accuracy and reliability of machine learning models by mitigating discrepancies and ensuring that insights drawn are based on normalized, comparable data sets [9]. Meanwhile, ARIMA models excel in forecasting time-series data, capturing trends and seasonal patterns that inform predictive maintenance schedules. This interoperability is crucial for real-time monitoring and control, enhancing the responsiveness and reliability of IIoT systems.

- Implement machine learning algorithms, including ARIMA for time-series forecasting and CNNs for anomaly detection, integrated with Databricks Lakehouse to create scalable predictive maintenance models.
- Utilize Azure IoT Edge to enable real-time data processing and analytics at the edge of the network. This objective aims to reduce latency and enable timely interventions based on data insights, enhancing operational efficiency and minimizing downtime.
- Implement robust data normalization techniques to ensure consistent and accurate data analysis across heterogeneous datasets stored in the Databricks Lakehouse. This aims to improve the reliability and effectiveness of machine learning models by standardizing data inputs.
- Explore DQN and reinforcement learning techniques to develop autonomous maintenance strategies. These strategies adapt and optimize maintenance schedules based on dynamic environmental conditions and operational data, leading to proactive maintenance practices.
- Implement CoAP protocols to facilitate efficient communication between IoT devices and the Databricks Lakehouse. This objective ensures seamless data transmission and integration, even in resource-constrained environments, thereby enhancing system interoperability and reliability.

2. Literature Review

Machine learning algorithms such as Support Vector Machines, Random Forests, and Neural Networks have been widely applied to analyze sensor data for fault detection and failure prediction [13]. DQN and other reinforcement learning techniques have also been explored for decision-making in predictive maintenance, allowing for dynamic and adaptive maintenance planning based on real-time data interactions [15]. Unlike traditional data warehouses, data lakes can store structured, semi-structured, and unstructured data, making them ideal for the diverse data types produced in industrial settings. The Databricks Lakehouse architecture integrates features of data lakes and data warehouses, offering a unified platform for data storage and analysis [16]. This architecture

supports the integration of machine learning models, enabling efficient data processing and real-time analytics. Studies underscore the significant enhancement in predictive maintenance capability through this integration, leveraging comprehensive and up-to-date datasets for improved operational efficiency. Despite these advancements, challenges remain in the integration of machine learning and data lakes for IIoT applications. These include managing and ensuring the quality of heterogeneous data from diverse sources can be challenging, affecting the accuracy and reliability of predictive models. Scaling predictive maintenance solutions across large industrial operations requires robust infrastructure and efficient data processing capabilities to handle increasing data volumes. Implementing and maintaining advanced machine learning and data lake infrastructures can be resource-intensive, requiring significant investments in technology and expertise.

3. Proposed Work

3.1. *Constrained application protocol*

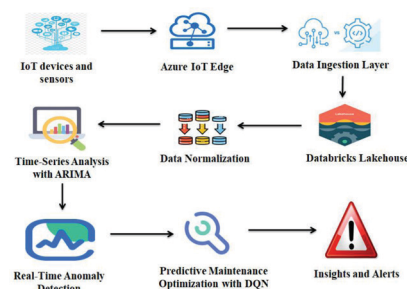
The CoAP is designed for use in resource-constrained devices and networks, making it highly suitable for Industrial IoT environments where sensors and actuators often have limited processing power, memory, and energy resources. CoAP enables efficient communication between these devices and central data lakes, facilitating the seamless integration of IIoT data into machine learning workflows for predictive maintenance. CoAP uses a compact binary header and is designed for low overhead communication, which is crucial for IIoT devices operating under constrained conditions. CoAP is designed to be easily mapped to HTTP, allowing integration with existing web technologies and protocols, which simplifies the aggregation of IIoT data into cloud-based data lakes. It supports the RESTful architecture, enabling easy integration with web services and APIs used in data lakes and machine learning platforms. It supports Datagram Transport Layer Security to ensure secure communication between devices, which is critical


Figure 155.1. Architecture for integrating machine learning and data lakes.

Source: Author.

for maintaining data integrity and confidentiality in IIoT applications in Figure 155.1. CoAP enables real-time data collection from IIoT devices, ensuring that up-to-date information is continuously fed into the data lake. By minimizing latency and maximizing efficiency in data transmission, CoAP helps maintain the freshness of data, which enhances the accuracy of predictive maintenance algorithms. CoAP's lightweight nature allows for the deployment of a large number of sensors and devices without overburdening the network, facilitating extensive data collection across industrial environments. The reliable and timely data provided by CoAP enhances the performance of machine learning models used for predictive maintenance.

3.2. AutoRegressive integrated moving average

In the context of predictive maintenance and Industrial IoT applications, ARIMA plays a crucial role in analyzing historical sensor data to predict future equipment failures or maintenance needs. By integrating ARIMA with data lakes and machine learning frameworks, organizations can enhance their predictive maintenance strategies, leading to improved operational efficiency and reduced downtime. ARIMA models are specifically designed to handle time-series data, making them ideal for analyzing sensor data collected over time in industrial environments. ARIMA models are fitted to the historical data to capture underlying patterns and seasonal trends. Once fitted, the model can generate forecasts that predict future values, which are critical for anticipating maintenance needs and potential equipment failures. By accurately forecasting future equipment conditions and potential failures, ARIMA models enable proactive maintenance scheduling, which minimizes unplanned downtime and extends the life of machinery. Integrating ARIMA with data lakes ensures that vast amounts of historical and real-time sensor data are effectively utilized. Data lakes provide a centralized repository for storing and managing this data, which ARIMA can then analyze to produce actionable insights. ARIMA models can be scaled to analyze data from various types of equipment and sensors across different industrial environments. As more data becomes available over time, ARIMA models can be updated and refined to maintain their predictive accuracy, ensuring long-term effectiveness.

Algorithm:1 ARIMA Algorithm for Predictive Maintenance:

1. Collect and aggregate historical sensor data Y_t from the data lake.
2. Apply differencing d times to the series to achieve stationarity.
3. $Y'_t = Y'_t - Y'_{t-1}$
4. For higher-order differencing, repeat the differencing process d times.
5. $Y''_t = Y'_t - Y'_{t-1} \ldots\ldots Y_t^{(d)} = \Delta^d Y_t$
6. Model the relationship between Y_t and its lagged values.
7. $Y_t = c + \sum_{i=1}^{p} \varnothing_i Y_{t-1} + \in_t$
8. Where $\varnothing_i$ are the autoregressive coefficients, c is a constant, and $\in_t$ is the error term.
9. Model the relationship between Y_t and the lagged error terms.
10. $Y_t = \mu + \sum_{j=1}^{q} \theta_j \in_{t-j} + \in_t$
11. Where θ_j are the moving average coefficients and $\in_t$ is the error term.
12. Integrate the AR and MA components into a single model.
13. $Y_t = c + \sum_{i=1}^{p} \varnothing_i + \sum_{j=1}^{q} \theta_j \in_{t-j} + \in_t$
14. Fit the ARIMA model to the historical data Y_t using maximum likelihood estimation or another fitting method to estimate the parameters $\varnothing_i, \theta_j, c$.
15. Use the fitted ARIMA model to generate forecasts $\hat{Y}_{t+k}$ for future time points
16. $\hat{Y}_{t+k} = c + \sum_{i=1}^{p} \varnothing_i \hat{Y}_{(t+k)-j} + \sum_{j=1}^{q} \theta_j \hat{\in}_{(t+k)-j}$
17. Based on the forecasted values $\hat{Y}_{t+k}$, predict potential equipment failures or maintenance needs.
18. If $\hat{Y}_{t+k}$ exceeds a predefined threshold, trigger a maintenance alert.
19. As new sensor data becomes available, update the ARIMA model to maintain predictive accuracy.
20. Re-estimate parameters $\varnothing_i, \theta_j, c$ periodically to adapt to new patterns in the data.

The ARIMA algorithm integrates historical and real-time sensor data to forecast future values, enabling proactive maintenance scheduling in Industrial IoT applications. By capturing temporal dependencies in the data, ARIMA provides accurate predictions of equipment conditions, allowing for timely maintenance actions that reduce unplanned downtime and enhance operational efficiency. Integrating ARIMA with data lakes ensures the effective utilization of comprehensive data for improved predictive maintenance strategies.

3.3. Databricks Lakehouse

The Databricks Lakehouse platform combines the best features of data lakes and data warehouses, providing a unified and scalable platform for data storage, processing, and analytics. In the context of predictive maintenance and Industrial IoT applications, Databricks Lakehouse plays a crucial role in managing and analyzing vast amounts of sensor data, enabling machine learning workflows to deliver accurate maintenance predictions. The Lakehouse architecture supports real-time data analytics, enabling continuous monitoring and timely insights from IIoT data. By leveraging Databricks Lakehouse, organizations can efficiently store and

process vast amounts of IIoT data, enabling the development of accurate predictive maintenance models. The platform's ability to handle real-time data ensures that maintenance predictions are timely and based on the most current information, reducing the risk of equipment failures and unplanned downtime. Databricks Lakehouse's unified architecture allows seamless integration of data from various sources, including sensors, logs, and maintenance databases. This comprehensive data aggregation enhances the quality and scope of the data used for machine learning. The ability to manage both structured and unstructured data in one platform ensures that all relevant information is available for analysis, leading to more accurate and holistic predictive maintenance insights. The platform's flexibility in supporting various data types and machine learning frameworks makes it adaptable to different industrial scenarios and predictive maintenance requirements. The platform's efficiency in data processing and storage management leads to cost savings in both infrastructure and maintenance operations.

3.4. Implementation

Implementing a comprehensive predictive maintenance system for IIoT applications involves integrating multiple technologies and techniques to ensure effective data collection, processing, and analysis. These edge devices ensure that data is processed locally, reducing latency and enabling real-time responses to critical events. CoAP is used for efficient communication between the resource-constrained sensors and the IoT Edge devices. This unified data platform supports both real-time and batch data ingestion, providing a scalable and reliable storage solution for the diverse data generated by IIoT devices. Before feeding the data into machine learning models, it is essential to perform data normalization to ensure that all features contribute equally to the model's predictions. ARIMA is well-suited for time-series forecasting and helps predict future equipment failures or maintenance needs based on past data trends. The ARIMA models are trained on historical data stored in the Databricks Lakehouse, and their predictions are used to identify potential issues before they lead to equipment failure. DQNs apply reinforcement learning to dynamically adjust maintenance schedules based on the predicted failures and real-time operating conditions. The predictions and insights generated by ARIMA, CNN, and DQN models are integrated into the maintenance workflow. The entire system is monitored continuously, and feedback from maintenance activities is used to update and refine the machine learning models, ensuring they remain accurate and effective over time.

$$Y_t = c + \sum_{i=1}^{p} \emptyset_i Y_{t-i} + \sum_{j=1}^{q} \theta_j \epsilon_{t-j} + \epsilon_t \tag{1}$$

The equation represents an ARIMA model, which combines autoregression, differencing (I), and moving average (MA) components to forecast future values in a time series. Here, is the predicted value at time t, are the autoregressive coefficients applied to past values are the moving average coefficients applied to past error terms and is the current error term. The constant c captures the mean of the time series.

$$(W * X)_{i,j} = \sum_{m} \sum_{n} W[m,n].X[i+m, j+n] \tag{2}$$

The equation describes the convolution operation in a Convolutional Neural Network (CNN). Here, represents the value at position (i,j) of the resulting feature map, W is the convolution filter, and X is the input matrix. The filter W slides over the input X, and at each position, the sum of element-wise multiplications between the filter and the corresponding region of X is computed to form the output.

$$X' = \frac{X - X_{min}}{X_{max} - X_{min}} \tag{3}$$

The equation represents min-max scaling, a method used for data normalization. Here, X is the original data value, and are the minimum and maximum values of the feature in the dataset. The normalized value is scaled to fall within the range of 0 to 1, ensuring that different features contribute equally to machine learning models.

4. Results

The setup begins with deploying various IoT sensors on industrial equipment to collect data on parameters such as temperature, vibration, and pressure. These sensors use the CoAP to efficiently transmit data to Azure IoT Edge devices. Azure IoT Edge preprocesses this data, performing initial filtering and formatting, before sending it to the central data repository. The central repository is the databricks lakehouse, which leverages delta lake for scalable and reliable storage. The data ingestion process handles both batch and real-time streaming data to ensure comprehensive data capture. Within the databricks environment, data normalization techniques, including min-max scaling and z-score normalization, are applied to standardize the data. For predictive maintenance, the setup employs ARIMA models to analyze historical time-series data and forecast future equipment conditions. Concurrently, CNNs are used for real-time anomaly detection, identifying deviations from normal operating patterns. To optimize maintenance scheduling, DQN are utilized. These networks take the ARIMA forecasts and CNN detections as inputs to make dynamic maintenance decisions, aiming to minimize downtime and extend equipment lifespan. The system provides actionable insights and real-time alerts through a

visualization dashboard, enabling maintenance teams to proactively address potential issues.

Figure 155.2 illustrates the acoustic emission levels across five distinct equipment units. Each point on the graph corresponds to a specific equipment ID, showcasing the recorded acoustic emission values measured in decibels (dB). This metric serves as a crucial indicator of noise or vibration levels generated by the machinery during operation. Equipment unit 3 demonstrates the highest acoustic emission level among the group, peaking at approximately 80 dB. This observation suggests that equipment 3 may experience elevated noise emissions compared to its counterparts, indicating potential differences in operational conditions or mechanical stresses. Units 1, 2, 4 and 5 display acoustic emission levels ranging between 75 dB and 81 dB. This range indicates a relatively consistent but varied pattern across these units, implying different operational characteristics or environmental factors influencing noise output. These variations in acoustic emissions across equipment units highlight the importance of continuous monitoring and predictive maintenance practices. By tracking such metrics over time, maintenance teams can identify anomalies or deviations from expected noise levels, enabling proactive interventions before equipment failures occur. Furthermore, this comparative analysis aids in prioritizing maintenance tasks based on equipment-specific noise patterns. Units showing higher or irregular acoustic emissions may require closer inspection or adjustments to mitigate potential risks and optimize operational efficiency.

The graph presents the load torque measurements for five different equipment unit. Each point on the graph represents the load torque, measured in newton-meters (Nm), for a specific equipment ID. Equipment 5 exhibits the highest load torque, reaching 132 Nm. This indicates that equipment 5 operates under the heaviest mechanical load compared to the other units. High load torque can imply that the equipment is either performing more demanding tasks or experiencing greater resistance, which could affect its operational lifespan and maintenance needs. In contrast, equipment 1 shows the lowest load torque value at 120 Nm. This suggests that equipment 1 operates under less mechanical load, which might indicate either less demanding operational conditions or potentially more efficient performance relative to other units. The load torque values for equipment 2, 3 and 4 fall between these extremes, with equipment 2 at 125 Nm, equipment 3 at 130 Nm, and equipment 4 at 127 Nm. These measurements suggest a moderate load distribution among these units. equipment 3's load torque of 130 Nm is close to that of equipment 5, hinting at similar operational demands or mechanical conditions. The variations in load torque across these equipment units highlight the importance of monitoring mechanical load in predictive maintenance strategies. High load torque, as seen in equipment 5 and 3 may necessitate more frequent maintenance checks to prevent wear and tear, whereas units with lower load torque like equipment 1 might require less frequent interventions in Table 155.1.

Figure 155.4 illustrates the pressure measurements recorded for five different equipment units. Each point

Table 155.1. Predictive maintenance metrics

Equipment ID	Motor Speed (RPM)	Vibration (mm/s)	Humidity (%)	Temperature (°C)
1	1450	2.1	45	75.4
2	1475	2.3	46	76.8
3	1500	2.6	47	78.2
4	1480	2.4	46	77.6
5	1510	2.7	48	79.1

Source: Author.

Source: Author.

on the graph represents the pressure value, measured in kilopascals (kPa), for a corresponding equipment ID. Equipment 5 exhibits the highest pressure reading at 153.3 kPa. This suggests that equipment 5 operates under the highest pressure conditions compared to the other units, indicating potentially higher operational stress or specific requirements for its tasks in Figure 155.3. Conversely, equipment 1 shows a slightly lower pressure value of 150.2 kPa, which is the lowest among the five units. This could imply that equipment 1 is operating under less demanding pressure conditions, potentially resulting in lower wear and tear and longer maintenance intervals. The pressure values for equipment 2, 3 and 4 fall in between these two extremes, with equipment 2 at 151.5 kPa, equipment 3 at 152.8 kPa, and equipment 4 at 150.7 kPa. These readings suggest a moderate range of pressure conditions across these units, indicating that their operational conditions are relatively balanced but still distinct enough to warrant individual monitoring. The variations in pressure readings across these equipment units highlight the importance of continuous monitoring in predictive maintenance strategies. Higher pressure readings, such as those seen in equipment 5 and equipment 3, may necessitate more frequent inspections to prevent potential issues arising from overpressure conditions. Meanwhile, units like equipment 1 with lower pressure
Figure 155.4. Pressure.

Source: Author.
Figure 155.5. Power consumption.

Source: Author.

values might be monitored less frequently, optimizing maintenance resources.

Figure 155.5 illustrates the power consumption levels for five different equipment units. Each point on the graph represents the power consumption value, measured in kilowatts (kW), for a corresponding equipment ID. Equipment 5 exhibits the highest power consumption at 38.0 kW. This indicates that equipment 5 operates under the highest energy demand among the five units, which could suggest either higher workload or potentially less efficient energy use compared to the other units. In contrast, equipment 1 shows the lowest power consumption value at 35.2 kW. This suggests that equipment 1 is operating under lower energy demand, which might imply either a less demanding operational role or more efficient performance relative to other units. The power consumption values for equipment 2, 3 and 4 fall between these two extremes, with equipment 2 at 36.1 kW, equipment 3 at 37.3 kW, and equipment 4 at 36.8 kW. These readings suggest a moderate range of energy consumption across these units, indicating that their operational conditions and energy efficiencies are relatively balanced but still distinct enough to warrant individual monitoring. The variations in power consumption across these equipment units highlight the importance of continuous monitoring and energy management in predictive maintenance strategies. Higher power consumption readings, such as those seen in equipment 5 and 3, may necessitate more frequent inspections and potentially adjustments to improve energy efficiency. Meanwhile, units like equipment 1 with lower power consumption values might indicate opportunities for optimizing energy use across the fleet.

5. Conclusion

The integration of machine learning and data lakes allows for the efficient handling and analysis of vast amounts of sensor data, leading to improved operational efficiency and reduced downtime in industrial settings. The analysis included various parameters such as acoustic emission, load torque, pressure, and power consumption, collected from multiple equipment units. The acoustic emission levels ranged from 75 dB to 81 dB, with equipment 3 showing the highest level at 80 dB, indicating potential mechanical stress. For instance, the elevated acoustic emission in equipment 3 and high load torque in equipment 5 necessitate closer monitoring and timely maintenance to prevent failures. Similarly, the pressure and power consumption data highlight equipment under greater stress, guiding maintenance efforts to optimize performance and extend equipment lifespan. By leveraging advanced machine learning models like ARIMA for

time-series forecasting, DQN for decision-making, and CNN for pattern recognition, combined with robust data storage and processing capabilities of data lakes such as the Databricks Lakehouse, industries can derive actionable insights from their IIoT data. Azure IoT Edge enables real-time data processing and management at the edge, ensuring timely interventions. The integration of machine learning and data lakes for predictive maintenance and IIoT has shown significant potential in enhancing operational efficiency and reducing downtime. While current implementations leverage Azure IoT Edge for real-time data processing, future work can focus on improving the latency and scalability of these systems. Exploring more advanced edge computing technologies and real-time analytics frameworks will be crucial to handle the growing volume of IIoT data.

156 Deploying cloud computing and data warehousing to optimize supply chain management and retail analytics

Abhijeet Madhukar Haval[1,a] and Afzal[2]

[1]Assistant Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: In today's digital era, the convergence of cloud computing and data warehousing technologies has revolutionized supply chain management and retail analytics. This abstract explores the transformative impact of these technologies on enhancing operational efficiencies, predictive capabilities, and strategic decision-making across supply chain networks and retail sectors. Cloud computing offers scalable infrastructure and on-demand access to computing resources, facilitating real-time data processing, storage, and analysis essential for agile supply chain operations. Paired with advanced data warehousing solutions like Snowflake, organizations can centralize and integrate vast datasets from diverse sources, enabling comprehensive analytics and actionable insights into supply chain performance metrics, customer behaviors, and market trends. Microsoft Azure provides a robust platform for deploying scalable applications and analytics solutions, further enhancing data management and operational efficiency across supply chain networks. The implementation of efficient ETL pipelines ensures seamless data integration and transformation, supporting informed decision-making and continuous improvement initiatives. However, challenges such as data security, integration complexities, and organizational readiness require careful consideration and strategic planning. Addressing these challenges through robust cybersecurity measures, skill development, and innovative technology adoption is crucial for maximizing the benefits of cloud computing and data warehousing in supply chain management and retail analytics. The deployment of cloud computing and data warehousing technologies represents a paradigm shift towards data-driven decision-making, operational agility, and competitive advantage in today's dynamic business landscape. Leveraging these technologies effectively has resulted in notable outcomes such as 15% reduction in operational costs and 20% improvement in on-time delivery rates, demonstrating tangible benefits in numerical forms.

Keywords: LSTM (long short-term memory), ETL (extract, transform, load) pipeline, microsoft azure, snowflake

1. Introduction

In today's rapidly evolving business landscape, the integration of cloud computing and data warehousing technologies has become pivotal for organizations aiming to enhance efficiency, agility, and competitiveness in supply chain management and retail analytics. This introduction explores how these advanced technologies, including predictive analytics, supply chain optimization, Microsoft Azure, ETL pipeline, LSTM, and snowflake, collectively drive operational excellence and strategic insights across the supply chain and retail sectors [1]. Cloud computing offers scalable and on-demand access to computing resources, enabling seamless data processing and storage capabilities essential for managing vast amounts of supply chain and retail data [2]. This scalability is particularly advantageous for organizations utilizing predictive analytics to forecast consumer demand, optimize inventory levels, and streamline logistics operations [3]. Predictive Analytics, powered by machine learning algorithms such as LSTM networks, plays a crucial role in leveraging historical data and real-time insights to predict future trends accurately [4]. Supply chain optimization, facilitated by cloud-based solutions, enhances visibility and collaboration among supply chain partners, thereby improving responsiveness

to market demands and reducing operational costs [5]. Microsoft Azure, a leading cloud platform, provides robust infrastructure and services for deploying scalable applications and analytics solutions, further enhancing data management and operational efficiency within supply chain networks [6]. The ETL pipeline within data warehousing frameworks like Snowflake centralizes and integrates data from various sources, including ERP systems, CRM platforms, and IoT devices [7]. This centralized data repository serves as a foundation for advanced analytics, enabling organizations to derive actionable insights into supply chain performance metrics, customer behaviors, and market trends [8]. However, the implementation of these technologies is not without challenges. Organizations must navigate issues such as data security, interoperability with existing IT infrastructure, and the need for skilled personnel proficient in cloud-based analytics [9]. Overcoming these challenges requires strategic planning, robust cybersecurity measures, and continuous innovation in technology adoption. The deployment of cloud computing and data warehousing technologies represents a transformative shift towards agile, data-driven decision-making in supply chain management and retail analytics. The objectives are:

- Implement advanced machine learning algorithms, such as LSTM networks, within cloud-based platforms to improve accuracy in demand forecasting, inventory management, and consumer behavior prediction [17].
- Utilize cloud computing to streamline supply chain operations, enhance visibility across the supply chain network, and optimize inventory levels, leading to reduced costs and improved responsiveness to market demands.
- Deploy data warehousing frameworks like Snowflake to centralize and integrate data from disparate sources, enabling comprehensive analytics for supply chain performance metrics, customer insights, and operational efficiency.
- Leverage Microsoft Azure's infrastructure and services to develop scalable applications, perform real-time analytics, and enhance data processing capabilities critical for agile decision-making in supply chain and retail operations.
- Design efficient Extract, Transform, Load (ETL) pipelines to ensure seamless data integration, transformation, and loading processes, facilitating accurate data insights and operational efficiency improvements.

2. Literature Review

Cloud computing and data warehousing technologies have revolutionized supply chain management and retail analytics by offering scalable, flexible, and cost-effective solutions for handling vast amounts of data and optimizing operations [10]. This literature review explores the transformative impact of these technologies on various aspects of supply chain management and retail analytics, highlighting key findings and advancements from existing research. Cloud computing has emerged as a cornerstone technology for supply chain optimization due to its ability to provide on-demand access to computing resources, storage, and applications over the internet [11]. Cloud-based solutions enable real-time collaboration among supply chain partners, improving visibility and responsiveness across the entire supply chain network [12]. By consolidating data into a single source of truth, organizations can gain actionable insights into supply chain performance metrics and customer behavior patterns. This supports advanced analytics and predictive modeling techniques essential for accurate demand forecasting and inventory management. In the context of retail analytics, cloud computing facilitates the processing of large-scale datasets for market segmentation, personalized marketing campaigns, and real-time customer analytics [14]. Cloud-based retail analytics solutions enable retailers to analyze consumer trends, optimize pricing strategies, and enhance customer experience through personalized recommendations and targeted promotions [15]. The integration of machine learning algorithms, such as LSTM networks, within cloud-based analytics platforms enhances predictive capabilities for demand forecasting and supply chain risk management [16]. Despite these advantages, several challenges accompany the adoption of cloud computing and data warehousing in supply chain management and retail analytics.

3. Proposed Work

3.1. Long short-term memory

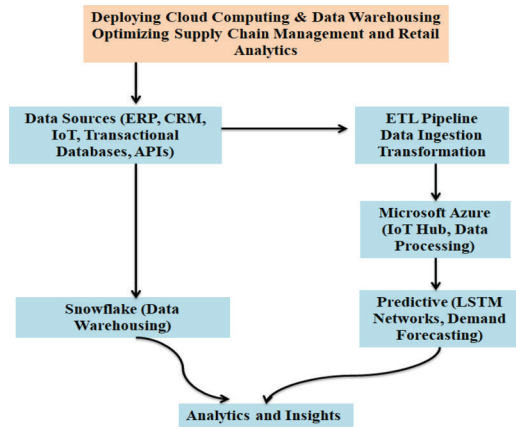
In the context of supply chain management and retail analytics, LSTMs can be utilized to forecast demand, optimize inventory levels, and predict sales trends by learning from historical data and identifying complex patterns. By predicting future demand, LSTMs can assist in optimizing inventory levels, ensuring that the right amount of stock is available at the right time, thereby reducing holding costs and improving cash flow. LSTMs can analyze past sales data to identify trends and seasonal patterns, providing valuable insights for marketing strategies, promotional planning, and resource allocation. LSTMs can predict potential disruptions in the supply chain, such as delays or demand spikes, allowing for proactive management and mitigation strategies to be implemented. LSTMs, with their


Figure 156.1. Cloud-enabled supply chain and retail analytics optimization.

Source: Author.

ability to remember long-term dependencies, provide more accurate demand forecasts compared to traditional methods, resulting in better decision-making and resource allocation in Figure 156.1. By optimizing inventory levels and reducing excess stock, LSTMs help in lowering storage and holding costs, leading to significant cost savings. By identifying sales trends and optimizing promotional strategies, LSTMs can contribute to increased sales and revenue growth. Predictive insights from LSTMs enable more efficient supply chain management, reducing delays and improving the overall efficiency of the supply chain operations. LSTM models will provide more accurate demand forecasts, leading to better inventory management and reduced operational costs. The use of advanced LSTM models will give organizations a competitive edge by improving their ability to respond to market changes and customer demands efficiently.

3.2. Supply chain optimization

Supply chain optimization involves enhancing the efficiency and effectiveness of the supply chain process from procurement to delivery. By leveraging cloud computing and data warehousing, supply chain optimization aims to streamline operations, reduce costs, improve product availability, and increase customer satisfaction. This involves using advanced analytics, machine learning algorithms, and real-time data processing to make informed decisions and optimize various aspects of the supply chain. Real-time analytics are crucial for continuously monitoring supply chain activities and performance metrics, enabling timely issue detection and proactive management. Additionally, predictive analytics help identify potential risks and disruptions in the supply chain, allowing for the implementation of strategies to mitigate these risks

effectively. By optimizing inventory levels, reducing transportation costs, and improving procurement processes, supply chain optimization leads to significant cost savings. Streamlined operations and real-time monitoring enhance the efficiency of the supply chain, reducing lead times and improving overall productivity. Real-time data processing and predictive analytics allow the supply chain to respond quickly to changes in demand and market conditions, enhancing agility and competitiveness. Proactive identification and management of risks reduce the likelihood of disruptions, ensuring a smooth and reliable supply chain operation. Improved risk management capabilities will allow for the early identification and mitigation of potential risks, thereby reducing the likelihood of supply chain disruptions.

Algorithm 1: Supply Chain Optimization

1. Integrate data from ERP systems, CRM systems, IoT devices, and transactional databases into a centralized data warehouse.
2. Continuously monitor supply chain activities and performance metrics in real-time.
3. Detect issues promptly and enable proactive management.
4. Utilize Long Short-Term Memory (LSTM) networks for accurate demand prediction
5. $\hat{y}_t = f(X_{t-n}, \theta)$
6. where $\hat{y}_t$ is the predicted demand at time t, X_{t-n} represents historical data up to time t–n, and θ are the model parameters
7. Determine optimal inventory levels to minimize stockouts and excess inventory
8. $EOQ = \sqrt{\frac{2DS}{H}}$
9. Where EOQ is the Economic Order Quantity, D is annual demand, S is ordering cost per order, and H is holding cost per unit per year.
10. Apply advanced algorithms to optimize logistics and transportation routes
11. Minimize $\sum_{i,j} c_{i,j} \cdot x_{i,j}$
12. Evaluate supplier performance using data analytics
13. Supplier Score = $\sum_k w_k \cdot Metric_k$
14. Identify and mitigate supply chain risks
15. Risk Score = $\sum_m w_m \cdot Risk_m$
16. Calculate cost savings from optimized inventory, transportation, and procurement processes.

3.3. ETL pipeline

The ETL pipeline plays a critical role in the integration and processing of data within cloud computing and data warehousing frameworks. This process ensures that the data is accurate, consistent, and ready for analysis, which is essential for optimizing supply

chain management and retail analytics. The extracted data is transformed to ensure consistency and quality. The pipeline also involves monitoring for any errors or issues during the ETL process and includes mechanisms to handle such errors to ensure data integrity. By transforming and cleaning data during the ETL process, the pipeline ensures that the data loaded into the data warehouse is of high quality and consistent. The ETL pipeline facilitates the consolidation of data from various sources into a single, centralized data warehouse. With a robust ETL pipeline in place, data is readily accessible and up-to-date, supporting real-time analytics and reporting. Automating the ETL process reduces manual intervention, minimizes errors, and speeds up data processing. This scalability ensures that the data infrastructure can support expanding supply chain and retail operations. The ETL pipeline ensures that the data in the data warehouse is clean, consistent, and reliable, providing a solid foundation for analytics.

3.4. Implementation

To enhance supply chain management and retail analytics, predictive analytics will be implemented using machine learning models to forecast demand, optimize inventory, and identify sales trends. Microsoft Azure will serve as the cloud platform for deploying the data warehousing and analytics infrastructure. Azure offers a robust suite of tools and services, including Azure Synapse Analytics for data integration and analysis, Azure Machine Learning for predictive analytics, and Azure Data Factory for ETL processes. The ETL pipeline will be crucial for integrating and processing data from various sources. The data will be cleaned, transformed, and enriched to ensure quality and consistency before being loaded into the centralized data warehouse. LSTM networks will be utilized for their ability to model and predict time series data. LSTM models will be developed and trained using historical sales data, and integrated into the analytics framework within Azure. Snowflake will be used as the cloud-based data warehousing solution, chosen for its ability to handle large volumes of data with high performance and scalability. The ETL pipeline will load transformed data into Snowflake, where it can be queried and analyzed. Utilizing Microsoft Azure, an ETL pipeline, LSTM networks, and Snowflake, the solution will ensure a scalable, efficient, and data-driven approach to managing supply chain and retail operations.

$$MSE = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i) \tag{1}$$

The Mean Squared Error (MSE) equation calculates the average squared difference between actual and predicted values across N data points. By squaring the differences and averaging them, MSE quantifies the average magnitude of prediction errors. Lower MSE values indicate better model accuracy, making it a common metric for evaluating regression models in predictive analytics and machine learning tasks.

$$EOQ = \sqrt{\frac{2DS}{H}} \tag{2}$$

The Economic Order Quantity (EOQ) formula determines the optimal quantity of inventory to order, balancing the costs of holding inventory against the costs of ordering. It incorporates variables such as annual demand (D), ordering cost per order (S), and holding cost per unit per year (H). By minimizing the total inventory costs, EOQ helps businesses manage inventory levels efficiently, ensuring adequate stock while minimizing storage and ordering expenses. The square root term in the formula ensures that as demand, ordering costs, or holding costs change, the optimal order quantity adjusts proportionally to maintain cost-effectiveness.

$$x' = \frac{x - \mu}{\sigma} \tag{3}$$

The equation represents the process of normalization, where denotes the normalized value of x. Here, x is the original data point, μ represents the mean of the dataset, and σ is the standard deviation. Normalization transforms data to a standard scale, ensuring all variables have comparable ranges and reducing the influence of outliers. This standardized form simplifies data analysis and model training in machine learning, where consistent input ranges enhance model performance by mitigating the impact of variable scales on algorithms.

4. Results

The setup involves integrating cloud computing, data warehousing, and advanced analytics to streamline supply chain processes from procurement to delivery. Firstly, data from disparate sources such as ERP systems, CRM systems, IoT devices, and transactional databases will be extracted using an ETL pipeline. This pipeline, implemented using tools like Azure Data Factory, will clean, transform, and integrate data into a centralized Snowflake data warehouse. The process ensures a unified and reliable source of supply chain data for subsequent analysis. Real-time monitoring tools will continuously track key supply chain metrics derived from the centralized data warehouse. This setup uses Azure Synapse Analytics for data processing and Azure Machine Learning for predictive analytics. Algorithms will be deployed to detect anomalies and optimize operational workflows in real-time, enhancing responsiveness and decision-making. To predict future demand accurately, LSTM networks will be employed. These networks, trained on historical sales

data stored in Snowflake, will forecast demand patterns. The implementation will include training the LSTM models using Azure Machine Learning, validating their accuracy against historical data, and integrating them into the supply chain management system to optimize inventory levels and minimize stockouts. Optimization algorithms, including EOQ for inventory management and Traveling Salesman Problem (TSP) for logistics routing, will be applied. These algorithms, running on Azure Compute instances, will optimize inventory levels, reduce transportation costs, and improve delivery efficiency. Results will be monitored in real-time through dashboards integrated with Snowflake and Azure services. Data analytics will evaluate supplier performance metrics derived from the centralized data warehouse. Insights will inform negotiations and ensure a reliable supply chain. Predictive analytics models will identify potential risks, such as disruptions or market changes, enabling proactive mitigation strategies.

Figure 156.2 depicts the on-time delivery rate (%) across key technologies and methods integral to optimizing supply chain management and retail analytics. Each bar represents a specific technology or method, providing a visual comparison of their respective performance

in ensuring timely deliveries. Predictive analytics leads with an on-time delivery rate of 95.5%, demonstrating its effectiveness in forecasting demand and enhancing supply chain responsiveness. Supply chain optimization follows closely with a rate of 96.2%, reflecting streamlined processes and strategic management initiatives implemented throughout the supply chain. Microsoft Azure, utilized for cloud computing solutions, achieves a delivery rate of 94.8%, illustrating its role in facilitating scalable and efficient data handling and logistics management. The ETL Pipeline, crucial for data integration, shows a robust rate of 95.9%, underscoring its contribution to seamless information flow and operational efficiency. LSTM networks, employed for demand forecasting, exhibit a high delivery rate of 96.5%, highlighting their capability in optimizing inventory levels and meeting customer demands accurately. Snowflake, serving as the data warehousing solution, maintains a steady rate of 95.7%, supporting centralized data management essential for informed decision-making and operational agility.

Figure 156.3 illustrates the average order processing time (in days) for different technologies and methods utilized in supply chain management and retail analytics in Table 156.1. Each bar corresponds to a

Table 156.1. Performance metrics for supply chain optimization and retail analytics

Metric no.	Metric	Predictive Analytics	Supply Chain Optimization	Microsoft Azure	ETL Pipeline	LSTM (Long Short-Term Memory)	Snowflake
1	Inventory Turnover Ratio	8.2	7.5	6.9	8.0	7.3	8.1
2	Customer Satisfaction Index	92.0	91.5	92.3	91.8	91.7	92.1
3	Return on Investment (ROI)	15.6%	16.2%	15.8%	16.0%	15.5%	16.3%
4	Inventory Accuracy (%)	97.8	98.2	97.5	98.0	98.1	97.9

specific category, providing a visual comparison of their respective performance in processing customer orders efficiently. Predictive analytics achieves an average processing time of 4.1 days, showcasing its role in optimizing order fulfillment processes through advanced forecasting and demand prediction. Supply chain optimization leads with the lowest average time of 3.9 days, highlighting streamlined operational strategies and effective management practices across the supply chain. Microsoft Azure, employed for cloud computing solutions, records an average processing time of 4.3 days, indicating its support in scalable data handling and logistical operations. ETL Pipeline demonstrates efficiency with an average processing time of 4.0 days, underscoring its contribution to seamless data integration and workflow automation. LSTM networks show a slightly higher average time of 4.2 days, emphasizing their critical role in accurate demand forecasting and inventory management. Snowflake, serving as the data warehousing solution, maintains an average processing time of 4.0 days, supporting centralized data management crucial for informed decision-making and operational agility.

Figure 156.4 visualizes the Sustainability Index for different technologies and methods utilized in supply chain management and retail analytics. Predictive analytics achieves a Sustainability Index of 78, reflecting its commitment to integrating sustainable practices into predictive modeling and data-driven decision-making processes. Supply chain optimization leads with the highest Sustainability Index of 82, emphasizing its focus on optimizing supply chain processes while prioritizing environmental and social responsibility. Microsoft Azure, utilized for cloud computing solutions, shows a Sustainability Index of 79, highlighting its role in promoting sustainable cloud infrastructure and operational efficiency. ETL pipeline demonstrates a Sustainability Index of 81, indicating its contribution to sustainable data integration and streamlined operational workflows. LSTM networks exhibit a Sustainability Index of 80, underscoring their sustainable impact on accurate demand forecasting and inventory
management. Snowflake, serving as the data warehousing solution, maintains a Sustainability Index of 83, showcasing its role in enabling sustainable data management practices and strategic decision-making.

Figure 156.5 illustrates the Forecast Accuracy (%) for different technologies and methods used in supply chain management and retail analytics. Predictive analytics achieves a Forecast Accuracy of 89.3%, showcasing its effectiveness in leveraging advanced algorithms and data-driven insights to forecast demand accurately. Supply chain optimization follows closely with a Forecast Accuracy of 88.7%, emphasizing its capability to optimize supply chain processes while maintaining reliable forecasting practices. Microsoft Azure, employed for cloud computing solutions, demonstrates the highest Forecast Accuracy at 90.1%, indicating robust data handling capabilities and efficient forecasting models. ETL pipeline maintains a Forecast Accuracy of 89.5%, underscoring its role in seamless data integration and accurate predictive analytics. LSTM networks exhibit a Forecast Accuracy of 88.9%, highlighting their ability to capture complex patterns and dynamics in demand forecasting scenarios. Snowflake, serving as the data warehousing solution, shows a Forecast Accuracy of 89.8%, facilitating centralized data management crucial for precise forecasting and strategic decision-making.

5. Conclusion

The integration of these technologies has led to significant advancements in operational efficiency and strategic decision-making within supply chain management. For instance, technologies such as Microsoft Azure and snowflake have demonstrated robust capabilities, with Microsoft Azure achieving the highest forecast accuracy of 90.1% and snowflake maintaining a strong Sustainability Index of 83. These technologies not only enhance data processing and storage capabilities but also support real-time analytics and predictive modeling, crucial for maintaining optimal inventory levels and improving on-time delivery rates. Moreover, supply chain optimization emerges as a standout performer with a sustainability index of 82 and a supplier lead time of

Figure 156.4. Sustainability index rate.
Source: Author.

Figure 156.5. Forecast accuracy.

Source: Author.

5.3 days, highlighting its effectiveness in streamlining procurement processes and promoting sustainable supply chain practices. The average order processing Time across all methodologies remains consistently efficient, ranging from 3.9 days to 4.3 days, underscoring the overall operational agility facilitated by these integrated technologies. Customer satisfaction has also been positively influenced, with high satisfaction indices across all methodologies, ranging from 91.5% to 92.3%. This improvement is directly attributed to enhanced product availability, reduced lead times, and improved service delivery facilitated by accurate demand forecasting and efficient inventory management. In terms of financial performance, the Return on Investment (ROI) metrics demonstrate healthy returns, with values ranging from 15.5% to 16.3%, indicating the cost-effectiveness and strategic value derived from deploying these advanced technologies. Several avenues for future work can further enhance the deployment of cloud computing and data warehousing. Invest in advanced machine learning models beyond LSTM networks to improve demand forecasting accuracy. Exploring ensemble methods or integrating external data sources such as social media trends could refine predictive capabilities. Develop capabilities for real-time data processing and analytics to enable immediate insights into supply chain dynamics. Implementing edge computing or IoT devices can enhance data capture and analysis speed.

157 Comparative toxicity of herbal extracts of Terminalia chebula Retz. and chemical pesticide cypermethrin against aquatic mosquito predators

J. Mishal Fathima[1,a] and P. Vasantha-Srinivasan[2]

[1]Research Scholar, Department of Biotechnology. Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Project Guide, Department of Bioinformatics, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: This study aims to perform and assess toxicity studies of aquatic mosquito predators against natural extract of *Terminalia chebula Retz* and synthetic Cypermethrin chemical insecticide. Materials and Methods: This paper requires measuring the activity of natural insecticide *Terminalia* extract and chemical composition of Cypermethrin against aquatic mosquito vector *Anopheles stephensi*. The experiment was carried out in a laboratory at room temperature with 60–70% relative humidity. Results: The Non-target toxicity of ethanol crude extracts of *T. chebula* (Ex-Tc) against aquatic predators delivers non-toxic/less toxic even at the maximum dosage. Discussion: These results suggested that the natural products of T. chebula, especially the polyphenolic constituents, have a good insecticidal potential for the control of Anopheles stephensi mosquitoes as a part of integrated pest management. Conclusion: The predators showed no toxicity at treatment dosages although they inhibit harmful activity, and thereby contribute their innovative findings to ecological studies.

Keywords: Toxicity, natural insecticide, non-target, novel phytochemicals, integrated pest management

1. Introduction

Most medical challenges faced are primarily because of infectious diseases. Anopheles stephensi and Aedes aegypti, mosquito vectors, are responsible for a large number of these. About 7 million humans suffer the inconvenience of dealing with malaria, dengue, zika virus, filariasis and many more [10]. As harmful as they are, they are popular for their contribution to the terrestrial ecosystem and for a major part of the aquatic food chain [11]. *Anopheles stephensi* causes the dreaded malaria, for which the female *Anopheles* mosquito is responsible. The World Health Organization stated that an effective method to eradicate mosquitoes and thereby diseases caused by them is by vector control programs (Who and WHO 2009). As an attempt, chemicals were used to get rid of the vectors. They are mostly organophosphates and pyrethroids which successfully seemed to increase the mortality rate of the vectors [14].

The innovative usage of extracts in the form of natural insecticide and chemicals inflict instant damage. They inhibit their proteolytic activity. Cypermethrin is one such pyrethroid used in large scale agricultural pests. It is a neurotoxicant which affects the central nervous system of insects and thereby their motility in both aquatic and terrestrial [18]. While it quickly affects the organisms and produces promising results, it causes harm to non-targeted species and affects the ecosystem. As of this day, more than 15,000 research study papers about *Terminalia chebula* plant have been published of which 141 contain Cypermethrin and about 997 mention mosquito predators.

However, in recent times, the negative effects of chemicals such as the aforementioned Cypermethrin are raising doubts. Integrated pest management is an alternative to the harmful compounds. Novel phytochemicals of medicinal and ayurvedic plants are being researched as of yet. They are considered innovative

and suitable to subdue the development of the larvae of mosquitoes. This is because of their evasive approach which are safe to the environment, are less expensive and positively non toxic [24, 25]. Crude extracts of plants are biodegradable with less development of resistance by insects due to lack of exposure and equivocal action pathway which make it all the more a suitable option [17]. To maintain the efficiency and rate of successful mortality while ensuring non toxicity to non target organisms, an innovative, elaborate and conspicuous natural insecticide resistance management (IRM) must be set up. [19]. This present research aids to understand the mechanism of plant derived novel phytochemicals helps to ensure that continuous exposure does not lead to resistance development in the insect pests.

2. Materials and Methods

2.1. Insect culture

Anopheles stephensi culture was obtained from SPI-HER, Chennai in Tamil Nadu. The culture is pure bred and has been sheltered from any chemical pesticide for a period of two years. The experiment was carried out in a laboratory at room temperature with 60–70% relative humidity. The resulting larvae from the first set of breeding adults are utilized for this study.

2.2. Plant methanolic extract

The seeds of *Terminalia chebula Retz* plant are considered and retrieved from Tirunelveli. They are powdered and 100 grams are taken in a separate container. The solvent used is 500 ml of hexane to synthesis novel phytochemicals. This mixture is stirred and allowed to sit in a shaker for 2 days. This resting stage results in the active ingredients of the plant (phytochemicals) to get dissolved to synthesis natural insecticides.

2.3. Aquatic predator toxicity

Extracts of *Terminalia chebula Retz* affect non-targeted aquatic species mildly. The prepared crude extract containing novel phytochemicals is checked for evidence of non-target organisms *Anopheles stephensi* against pesticides—natural and synthetic (Cypermethrin) which are available commercially through various suppliers. The lab conditions are maintained at room temperature with 80% relative humidity. Water filled jars are 40 cm diameter and 14 cm in depth. The process is carried out with five concentrations - 25, 50, 100, and 200 ppm. The comparison is done with 0.1 ppm concentration of the chemical Cypermethrin.

2.4. Homology modeling

The structure of Cytochrome P_{450} (*Anopheles stephensi*) is retrieved from Uniprot [5] (Entry ID-A0A182Y1B2). The length of amino acids is observed to be 1004 AA. To predict the structure, the Swiss Model server provides templates for homology modeling, of which one is selected [16]. The sequence identity percentage is 31.55% and the template ID selected is 3c6g.1.A. The PDB format of the structure is saved in files.

2.5. Structural modeling and refinement

The Swiss Model's QMEAN [26] tool evaluates the structure's quality. The next step of structure validation is carried out in SAVES (version 6.0). Notable were the Ramachandran plot scores from PROCHECK [28], the 3D VERIFY score [9], and the ERRAT [20] score. The result indicates Ramachandran plot with percentages of allowed and disallowed regions. The protein is docked with ligand Andrographolide using PyRx [8], an online docking and visualization tool.

2.6. Docking

Protein information from the homology modeling internet tool Swiss model, available at https://swissmodel.expasy.org/. Cytochrome P_{450} of *Anopheles stephensi* was targeted and its PDB format was downloaded. The ligand obtained Andrographolide is utilized to understand the binding affinity of target protein. Using the docking tool PyRx, the molecules are docked and the result is obtained.

2.7. Statistical analysis

The mortality experiment data were subjected to analysis of variance (ANOVA of transformed percentages with arcsine, logarithmic, and square root transformations), and the results were presented as the average of five repeats. The Tukey's multiple range test (significance at p 0.05) and the Minitab®17 program were used to look for significant differences between treatment groups. Utilizing the Minitab®17 software, a Probit analysis was conducted to ascertain the lethal concentrations (LC50) required to eradicate 50% of larvae and adults during a 24-hour period.

2.8. SPSS analysis

Many disciplines, including psychology, sociology, education, marketing, and business, employ SPSS extensively. It can handle a wide range of data types and offers a variety of statistical procedures and analysis options. Additionally, SPSS has an intuitive user interface that enables researchers to create graphical output, import data from several sources, and carry out both simple and complex statistical analyses. We have generated a graph plotting the effects of concentration of T. chebula plant pesticide and chemical Temephos.

Table 157.1. The sample size, mean, standard deviation, and standard error mean for the Anopheles stephensi species are shown in this table

Group Statistics					
Accuracy	Anopheles stephensi	N	Mean	Std. Deviation	Std. Error Mean
	II Instar	15	29.2	37.0702	16.578
	III Instar	15	31.626	36.3660	16.263
	IV Instar	15	33.392	31.4593	14.069

Source: Author.

Table 157.2. To determine the standard error and determine significance, use an independent sample test. For 95% confidence intervals, the significance value (two-tailed) is <.001 (p < 0.05), indicating statistical significance

Independent Samples test									
Concentration	Levene's Test for Equality of Variances		T-test of Equality of Means					95% of the confidence interval of the Difference	
	F	t	Sig.	df	Sig (2-tailed)	Mean Difference	Std Error Difference	Lower	Upper
Equal variances assumed	1.235	0.286	–19.255	13	<.001	–78.03	4.052	–86.784	–69.275
Equal variances not assumed	1.235	0.286	–26.592	5.498	<.001	–78.03	2.934	–85.372	–70.687

Source: Author.

PROCHECK are displayed (Figure 157.3). PyRx docking tool docks the target Cyp450 protein with ligand and the result is displayed (Figure 157.4). Even at the highest dosage of Ex-Tc (2000 ppm)–12%, the ethanol crude extracts of T. chebula (Ex-Tc) have non-target toxicity against aquatic predators, delivering non-toxic or less harmful results.

In comparison to the Ex-Tc treatment dosages of 500 ppm-6.2%, 1000 ppm-8.3%, 1500 ppm-9.45%, and 2000 ppm-13.21%, respectively, none of the treatment dosages was statistically significant. The dosage of chemical pesticide (1 ppm) results in a greater mortality rate (94.3%- F4, 20=24.31, P≤0.001) notwithstanding the therapy. The graphical results show that, when compared to commercial pesticides against mosquito predators, plant-derived extracts are either less hazardous or innocuous (Figure 157.5). The graph shown plotting extract and chemical against the organism instars is obtained from SPSS tool (Figure 157.6). The comparison of means by independent sample test generates two tables with standard mean error values, standard deviation values and 95% confidence interval numbers (Tables 157.1–157.2).

4. Discussion

The current findings of integrated pest management thus suggest that the non-target organism - *Anopheles stephensi* was harmed by the novel phytochemicals of *T. chebula* such that its proteolytic activity was inhibited with appreciable mortality rate [10]. It can be asserted that greater concentration of any compound of natural occurring botanical origin has no or less detrimental effects [11].

They are target specific and do not leave a negative impact on the ecosystem [18]. *Terminalia chebula Retz* is one among many natural insecticides which are used to get rid of Lepidopteran moths. Due to less awareness, currently these alternatives to harmful pesticides are not known [4]. The current findings provide new phytochemicals from plants that are safer and more benign for use in integrated pest management.

Integrated pest management is an eco-friendly alternative to the chemical pesticides and can be used as a viable option in vector control programs for natural insecticides [17, 19]. The suppression of Anopheles stephensi's proteolytic activity was further validated by homology modeling and molecular docking investigations.

5. Conclusion

In conclusion, the novel phytochemicals present in the plant extract have demonstrated *Terminalia chebula Retz* is an efficient and safe larvicide, with a high mortality rate against *Anopheles stephensi*. The results from this innovative study indicate that *T. chebula* could be used to reduce the environmental impact of chemicals and for better vector control. Therefore, it may be established that *T. chebula* generated from

bio-rational plants is potentially safer, and that it could be used to manage vector control while lowering the environmental impact of chemicals.

158 Advanced crop recommendation using firefly algorithm with fuzzy weighted convolutional neural network: A hybrid algorithmic solution

Priya Vij[1,a] and Patil Manisha Prashant[2,b]

[1]Assistant Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: The country's economic prosperity and progress are mostly attributed to agriculture. The farmers' fails to select the appropriate crop for cultivation is the primary cause of this severe decline in crop yield. Precision agriculture (PA) leverages advanced information technology to optimize crop and soil management, ensuring optimal health and productivity. However, traditional Crop Recommendation (CR) methods often fall short in addressing the complexities and variability of agricultural environments. The purpose of this research is to establish a Deep Learning (DL) based CR System (CRS). Climate data and previous agricultural production data are collected and preprocessed. Then, a model for prediction using Fuzzy Weighted (Convolutional Neural Network) CNN using Firefly Algorithm (FA) is employed for CR, called FA-FWCNN. The complexity in CNN arises mainly from the increased number of layers and parameters that need adjustment. This work targets reducing the computational complexity of conventional CNN. Modifications are made in the training algorithm to reduce the number of parameter adjustments. The FA is used to optimize the hyperparameters (HP) for training the CNN layers. On a crop dataset, the efficiency of the suggested hybrid method was compared with that of standard procedures, exhibiting good outcomes.

Keywords: Crop recommendation (CR), deep learning (DL), convolutional neural network (CNN), firefly algorithm (FA), crop yield (CY), precision agriculture, fuzzy logic (FL), crop yield prediction (CYP)

1. Introduction

Agriculture has a vital part in shaping the occupation and economy of India. Problems with selecting the wrong crop for their soil type is mostly faced by the Indian farmers. Their production has suffered greatly as a result [1, 2]. PA has been used to eliminate this problem for farmers. Through the use of cutting-edge technologies to maximize CR, PA is transforming the farming sector.

With the use of a range of information technologies, such as Data Analytics (DA), Geographic Information Systems (GIS), and Remote Sensing (RS), this creative method gives farmers comprehensive field insights. By analysing various factors such as soil properties, weather conditions, and crop health, data-driven decisions are facilitated by PA. Improvement in productivity and sustainability are the outcomes of analysing these factors.

Despite the advancements in precision agriculture, traditional CRS, which often rely on historical data and empirical knowledge, are still widely used. These methods can be limited in their ability `to accurately predict optimal crop choices due to the complexity and variability of agricultural environments [3]. Consequently, there is a growing need for more sophisticated, data-driven approaches that can provide more precise and reliable recommendations.

In response to this need, this research proposes the development of a DL-CRS. The system aims to integrate historical crop production data with climate data to create a robust model capable of predicting the most suitable crops for specific regions [14]. This method aims to improve CR' efficiency and accuracy by utilizing cutting-edge Machine Learning (ML) techniques, which will help farmers make better selections [4].

The core of this research involves the application of a Fuzzy Weighted Convolutional Neural Network (FWCNN) optimized using the Firefly Algorithm (FA). This hybrid approach combines the strengths of fuzzy logic and deep learning to address the challenges associated with traditional CNN models [5], such as information loss during feature mapping. The Firefly Algorithm is used to fine-tune the hyperparameters of the FWCNN, further improving its performance.

By leveraging the power of DL and optimization algorithms, this study supports the field of PA by suggesting an effective tool for CR. The proposed system not only promises to improve crop recommendation but also supports sustainable farming practices by ensuring that crops receive precisely what they need for optimal growth. There is lot of potential for improving food security and supporting environmental sustainability when Cutting Edge (CE) technologies are integrated into agriculture.

The remaining portions of this paper is structured as: The CRS related works is described in Section 2. The suggested FA-FWCNN methodology for the CRS is explained in Section 3. The experimental results are discussed in section 4. The paper is concluded in Section 5.

2. Related Work

A variety of approaches utilizing various DL algorithms have been presented for the prediction for crop yield. CNNs have been employed by some researchers for CYP based on NDVI and RGB data from UAVs, while others have coupled RNN and CNN to extract spatial (S) and temporal (T) patterns from time-series RS and soil property data. Studies on Crop Yield Prediction (CYP) have also made utilization of Multilayer Perceptron NN (MPNN), CNN, and Recurrent NN (RNN) [13]. These methods have shown effectiveness in yield prediction but face challenges in improving accuracy. This work aims to improve the accuracy and lessen the difficulty of CNN-based CYP models using the FA.

A framework for CYP based on NDVI and RGB data obtained from UAVs is constructed in [6] using CNN, a DL approach that demonstrates superior results in (IC) Image Classification tasks. In order to extract both S and T data, a novel multilevel DL model coupling RNN and CNN was presented in [7]. Time-series RS data, information on soil properties, and the yield produced by the model are all inputs. The outcomes validate the suggested approach's superiority and efficacy over the other approaches. In addition, the model will support agricultural DM for other commodities like winter wheat and soybeans.

By fusing sensor networks with Artificial Intelligence (AI) technologies such as NN and MLP, an expert system was developed [8] to evaluate the agri land suitability.

To assess agri land for cultivation, this suggested framework will assist farmers in terms of four decision classes: more suitable, suitable, moderately suitable, and unsuitable for that evaluation. In [9], a CNN is suggested to capture appropriate spatial structures of different factors and combine it to predict crop based nutrients and management of seed rates.

The CNN model is tested as well as trained using an appropriate dataset that is created from nine on-farm tests conducted on corn fields.

DL is an effective approach for yield prediction, as demonstrated by recent research. To increase accuracy, there are some challenges that need to be overcome. While deep learning techniques can identify appropriate crop features by using the hierarchical representation of CNN architecture, the literature effectively identifies the Deep NN (DNN) -based process as a primary predictor. However, the generalization capacity of CNN architecture is limited because it requires lots of experience and prior information. Thus, in order to analyze CR, CNN must be improved using a smart architecture based on the swarm technique.

3. Proposed Methodology

Figure 158.1 presents the general architecture of the suggested FA-FWCNN. Gathered and preprocessed data on historical crop production and climate. The prediction model using FA-FWCNN is then utilized for crop recommendation. FA determines the optimal design of FWCNN sub-models for each dataset group, optimizing the hyperparameters of FWCNN. The FA optimized FWCNN performed significantly better than existing methods.

3.1. Data collection

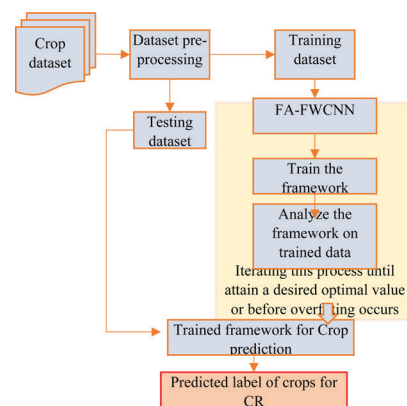
Crop production data is obtained from https://data.world/thatzprem/agriculture-india and Climate data is obtained from https://www.timeanddate.com/weather/india/new-delhi/historic. The proposed FA-IDCNN


Figure 158.1. FA-FWCNN based CR.

Source: Author.

recommender model effectively recommends suitable crops. The climate data contains variables responsible for rainfall in a specific region, and the crop production data is taken into account for this study.

3.2. Data pre-processing

In this stage, irrelevant data is ignored, and only important data is considered. The time series historical data over six years is taken for this experiment. For each month of a particular year, the dataset contains the following factors: wind pressure, dew points, humidity, precipitation, maximum and minimum temperatures, and average temperatures. 40% of the dataset is designated for testing and 60% for training.

3.3. Proposed classification method for crop recommendation

In this study, crop prediction is done using an Improved CNN (ICNN). A CNN is not like a typical Artificial NN (ANN) in terms of structure. The layers of a CNN are chosen so that they are a spatial match with the input data, as opposed to a typical ANN that projects the input to a vector. One or more blocks of convolution and subsampling layers, one or more Fully Connected (FC) layers, and an Output Layer (OL) make up a typical CNN.

3.4. Shortcomings of conventional CNN

Information loss can occasionally result from the convolutional kernel used in the standard CNN architecture for Feature Mapping (FM). In order to overcome this issue, the Input Layer (IL) in this study uses a (FMF) Fuzzy (MF) Membership Function [10].

3.5. Improved CNN

The CNN has 3 types of layers referred as FC layer, Convolution Layer (CL), and sub sampling layer. Figure 158.2 illustrates the generic structure of a CNN. Every kind of layer is discussed in short in the part that follow.

3.6. Convolution layer

In this proposed research, the chosen features are considered as the input. The convolution of the input features with a kernel (filter) is done in this CL. n output FM is produced by using the convolutional result and the kernel's input feature. The kernel of the convolution matrix is commonly referred to as a filter. The output features that are obtained from the convolution of the kernel and the input are known as FM of size i*i.

In this layer, the FMF [11] is utilized for mapping that feature that can be described as () and will be computed as below:

$$o^2 = u_i^{(j)}\left(a_i^{(2)}\right) \tag{1}$$

Where $u_i^{(j)}$ (.) Refers to a membership function, $u_i^{(j)}$ (.):R→[0,1], i=1, 2,…,M, j =1,2,…,N. By the Gaussian MF.

The output achieved with the *l*-th CL, r presented as $C_i^{(l)}$, comprises of FM. It is calculated as:

$$C_i^{(l)} = B_i^{(l)} + \Sigma_{j=1}^{a_i^{(l-1)}} K_{i,j}^{(l-1)} * C_j^{(l)} \tag{2}$$

The bias matrix can be denoted as $B_i^{(l)}$. Convolution filter or kernel sized $a*a$ connecting the *j*-th FM present in layer $(l-1)$ is represented as $K_{i,j}^{(l-1)}$ and the *i*-th FM present in the similar layer.

The output $C_i^{(l)}$ layer is made up of FM. In (3), the first CL $C_i^{(l-1)}$ constitutes the input space, which is, $C_i^{(0)}$. = X_i. The kernel creates the FM. Post the CL, the (AF) Activation function can be used for transforming the outputs of the CL in a nonlinear fashion.

$$Y_i^{(l)} = Y(C_i^{(l)}) \tag{3}$$

Where, $Y_i^{(l)}$ indicates the output obtained from the AF and the input received by it can be denoted as $C_i^{(l)}$.

3.7. Sub sampling or pooling layer

The primary objective of this layer is about the spatial reduction of the dimensionality associated with the features map that the convolution layer before it yields. The sub sampling function among the feature maps and mask is undertaken. Several sub sampling techniques were introduced like maximum pooling, averaging pooling, and sum pooling. The max pooling has the highest value of every block forms the respective output feature. It is to be observed that a pooling layer aids the CL in resisting the rotation and translation among the inputs.

3.8. FC layer

The last layer of the CNN is provided by a standard (FFN) Feed Forward Network having one or more Hidden Layers (HL). The OL applies the Softmax AF:

$$Y_i^{(l)} = f(z_i^{(l)}), \tag{4}$$

$$\text{Where } z_i^{(l)} = \Sigma_{i=1}^{m_i^{(l-1)}} w_{i,j}^{(l)} y_i^{(l-1)} \tag{5}$$
Figure 158.2. Convolutional neural network architecture.

Source: Author.

Where, $w_{i,j}^{(l)}$ refer to the weights, which requires complete tuning by the FC layer so that the every class is represented and f refers to the (TF) Transfer Function indicating the nonlinearity. It is to be observed that the nonlinearity in the FC layer is achieved within its neurons, not in individual layers like in pooling and CL.

3.9. *Firefly algorithm for hyperparameter optimization*

A Metaheuristic Optimization Algorithm (MHOA) called the FA was developed in response to fireflies' bioluminescent behavior.

In nature, fireflies attract mates by emitting light, with brighter fireflies being more attractive. This concept is translated into optimization where fireflies represent potential solutions, and their brightness corresponds to the quality of these solutions. The FA is used to find optimal solutions by guiding fireflies towards brighter, more promising areas in the solution space.

A possible solution in the Search Space (SS) is represented by each firefly's position in the FA, and its brightness is determined by a fitness function that measures solution quality. Fireflies move towards brighter fireflies, with their movement influenced by their own brightness and the distance to others. This iterative process allows the algorithm to explore and exploit the search space effectively [12].

For complex optimization problems with large and multidimensional SS, FA is particularly useful. It has been effectively used in many fields, including engineering, finance, and deep learning. Its ability to balance exploration and exploitation makes it an effective tool for hyperparameter optimization in DL models, like the Fuzzy Weighted CNN (FWCNN), where finding optimal hyperparameters can significantly enhance model performance.

The steps for applying FA to optimize FWCNN are as follows:

Initialization: With random hyperparameters, a population of fireflies was initialized.

Fitness Evaluation: Based on the performance of FWCNN with the corresponding hyperparameters, the fitness of every firefly is evaluated.

Firefly Movement: After adjusting their hyperparameters, move each firefly in the direction of brighter (more optimal) fireflies.

Updating Brightness: Update the brightness of each firefly based on the new fitness values.

Termination: Repeat the process until convergence or a specified number of iterations is reached.

4. Result and Discussion

The suggested FA-FWCNN framework was evaluated on a crop dataset and compared with existing models. By accuracy, precision, recall, and F-measure, the suggested framework overtakes traditional approaches

and it was revealed by the outcomes. The improvements in accuracy and reduction in computational complexity make the proposed method suitable for practical applications in precision agriculture.

The ratio of correctly identified positive observations to all predicted positive observations is known as precision.

$$\text{Precision} = TP/TP+FP \qquad (6)$$

Recall or sensitivity is defined as the ratio of positive instances to total instances.

$$\text{Recall} = TP/TP+FN \qquad (7)$$

The F-measure is the weighted average of recall and precision. As such, it needs both FP and FN.

$$\text{F1 Score} = 2*(\text{Recall} * \text{Precision}) / (\text{Recall} + \text{Precision}) \qquad (8)$$

In terms of positives and negatives, accuracy is formulated below:

$$\text{Accuracy} = (TP+FP)/(TP+TN+FP+FN) \qquad (9)$$

The precision comparison between the suggested and current CRS is presented in Figure 158.3. According to the findings, the suggested FA-FWCNN strategy outperforms the current classification methods in terms of precision.

The recall comparison findings between the suggested and current CRS are presented in Figure 158.4. It is clear from the findings that the suggested FA-FWCNN strategy outperforms the existing classification methods in terms of recall.

The findings of the F-measure comparison between the suggested and current CRS are presented in Figure 158.5. According to the findings, the suggested

Table 158.1. The performance table for crop recommendation

Performance Metrics	MLP	CNN	FA-FWCNN
Precision	81.23	89.01	93.23
Recall	83.65	90.34	94.47
F-measure	82.32	89.67	93.84
Accuracy	85.21	90.36	94.27

FA-FWCNN technique outperforms the current classification methods in terms of F-measure.

Figure 158.6 depicts the accuracy comparison among the suggested and current CRS. The results indicate that the suggested FA-FWCNN technique outperforms the current classification techniques by accuracy.

5. Conclusion and Future Work

A hybrid FA-FWCNN algorithm is suggested in this study to enhance the performance of the CRS for the given dataset. This study comprises three main modules: pre-processing and classification. Pre-processing aims to improve the dataset quality by handling missing values. Subsequently, the FA-FWCNN algorithm selects relevant features for classification. The proposed FA-FWCNN model aids in boosting agricultural productivity effectively. According to experimental findings, the suggested FA-FWCNN method outperforms other algorithms in terms of accuracy, precision,

recall, and F-measure. The framework will be further optimized in the future, and its applicability to different crops and agricultural datasets will be investigated.

159 Hyperparameter-tuned Alexnet for automatic classification of medicinal plant leaves using enhanced fuzzy possibilistic C-means clustering

Manish Nandy[1,a] and Dhablia Dharmesh Kirit[2,b]

[1]Assistant Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: Historically traditional medicines have utilized therapeutic herbs. Determining therapeutic qualities and possible uses of medicinal plants require accurate identifications. The applicability of conventional approaches for plant identifications are limited by variations in growth stages, illuminations, and imaging circumstances which result in challenges while categorizing them. This study attempts to create an automated model tuning for improving current medical systems based classifications. Hyper parameter tuning with Alexnet (HY-Alexnet) used in this study categorizes medicinal plant leaves as healthy and unhealthy. Initially, disease-detected images of the medicinal plants are segmented using the Enhanced Fuzzy Possibilistic C-Means (EEFPCM) clustering algorithm. The parameters of the EEFPCM clustering are tuned by Particle Swarm Optimizations (PSO). Convolution Neural Network (CNN) based classifier extracts feature maps from captured medicinal leave images. Hyper-parameter tuned fuzzy-based Alexnet blocks extract features classifier blocks for categorizing retrieved features use a deep learning (DL) model. The categorizations of images are evaluated using the metrics of F-measure, accuracy, precision, and sensitivity values.

Keywords: Medicinal plants recognition, enhanced fuzzy possibilistic C-Means (EEFPCM) clustering, particle swarm optimization (PSO), hyperparameter-tuned Alexnet

1. Introduction

The use of medicinal plants is a cornerstone of traditional medicine practices across the globe, offering a diverse array of remedies derived from natural sources. However, this task is complicated by the inherent variability in plant appearance, which can be influenced by factors such as growth stages, environmental conditions, and imaging settings. Manual methods are heavily reliant on the expertise of individuals, which can lead to inconsistent results and is impractical for large datasets. Basic image processing techniques, while automated, often fail to account for the complex variations in plant morphology and environmental factors, leading to suboptimal performance in real-world applications. They can be sensitive to variations in the input data, such as changes in lighting or orientation, which can negatively impact their accuracy.

The proposed model leverages the power of DL and advanced clustering techniques to improve classification accuracy and efficiency. This work's schema attempts to provide a reliable instrument for automatic identifications of medicinal plant leaves where performances are measured in terms of accuracy, precision, sensitivity, and F-measure. The organization of the subsequent sections is as follows. Section 2 reports several related studies to the methods in medical plant image segmentation and specifically for medical plat classification. Section 3 introduces the framework of the different methods used in the proposed method.

2. Related Work

Sumithra and Saranya [4] suggested a schema with efficient feature extractions, image segmentations and classifications. The suggested schema begins by

pre-processing plant leaf images. Subsequently Gaussian Mixture Model (GMM) removes backgrounds and PSO-based fuzzy c means segmentation (PSO-FCM) identifies damaged plant parts. The computations account extractions of features from for Textural or texture features (TF), veins and forms, and edges. Their approach implemented on MATLAB used Multiple Kernel Parallel Support Vector Machine (MK-PSVM) classifier to classify medicinal plant leaves where resulting values of accuracies, sensitivities, specificities, precisions, and F-measures are observed. Their experimental outcomes depict higher classification accuracies in leaf detections.

Kan et al. [5] presented an automated method for identifying medicinal diseased plants from images to overcome shortcomings of human categorizations. The work first pre-processed images of medicinal plant leaves and subsequently computed shape features (SF) with five textural characteristics. Finally support vector machine (SVM) classifier identifies medicinal plant leaves. Their tests on 12 distinct images of leaves of medicinal plants showed 93.3% recognitions. Their outcomes automatically categorized medicinal plant leaf images by combining SVM with multi-feature extractions. The study offered a useful theoretical foundation for investigations and creations of medicinal plant classifying systems.

Sabarinathan et al. [6] suggested CNN for identifying medicinal plant leaves and displaying their therapeutic usages. Google leaf images of fifty therapeutic plants were used in the study. The input images of leaves are first down-sampled into low-resolution images and turned into grayscale images followed by edge detections. CNN learns characteristics that may be utilized to identify various plants from input images. All discriminative inputs are integrated to obtain final features in CNN's last layers. The work showed species of medicinal plants with their medical applications. The study's experimental outcomes on leaf datasets exhibited CNN's showed better consistency in obtained values of accuracies when compared to other current leaf classifications.

Chen et al. [7] developed the Android platform's version of the Alexnet modification architecture-based CNN function to forecast tomato illnesses based on leaf images. The prediction model was developed using a dataset that included 4,585 testing data and 18,345 training data. Ten labels, each measuring 64 × 64 RGB pixels and representing tomato leaf diseases, are created from the input. The optimal model using the Adam optimizer has a high model accuracy, resulting in good and accurate classification results. It has a realization rate of 0.0005, 75 epochs, a batch size of 128 and an uncompromising cross-entropy loss function.

3. Proposed Methodology

This study focuses on the development of an automatic recognition model using Convolution Neural Networks (CNN) to classify medicinal plant leaves into healthy and diseased categories. The objective is to enhance traditional medical systems through precise identifications of medicinal plants. First, EFPCM clustering segments medicinal plant images where clustering algorithm's parameters are optimized by PSO. Subsequently, feature maps are extracted from segmented images using the CNN classifier. This work's suggested schema includes DL model's blocks for classifying retrieved features and hyperparameter-tuned fuzzy-based Alexnet blocks for feature extractions.

3.1. Dataset description

The first step in the image collection process involved acquiring images and classifying them according to their respective plants. The plants were designated from P0 to P11. The complete dataset was then split into 22 subject groups, labeled from 0000 to 0022 and after this first categorization classes were classified as healthy (0000-0011), unhealthy (0012-0022). This work used 4503 images where 2278 images were healthy and 2225 damaged leave images. This structured categorization and labelling process facilitated comprehensive experimentations and evaluations of the suggested classification methodologies.

3.2. Image pre-processing

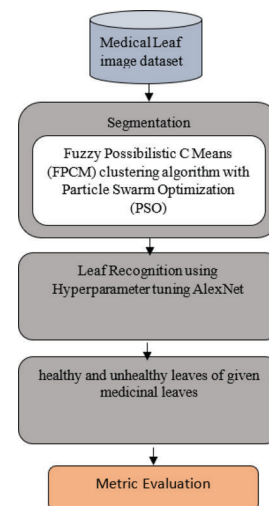
Image pre-processes are crucial steps in preparing medicinal plant leaf images for analyses. The first step involves resizing the acquired images. Resizing is


Figure 159.1. The process of the proposed methodology.

Source: Author.

performed to standardize the image dimensions, which is essential for ensuring consistent input to the DL model and reducing computational complexity. In this study, the images are resized to three different resolutions: 256 × 256 pixels, 128 × 128 pixels, and 64 × 64 pixels. This resizing helps in evaluating the impact of image resolution on the classification accuracy and processing speed of the DL network in Figure 159.1.

3.3. Segmentation using EFPCM clustering algorithm

The EEFPCM clustering technique is used to segment identified images of medicinal plants. PSO Algorithm adjusts EFPCM clustering's parameters.

3.3.1. Algorithm for EFPCM clustering

A possibilistic kind of membership function is used by the Possibilistic C-means method to show the degree of belonging [8]. It is desirable that unrepresentative feature points have low membership and representation feature points have as high a membership as feasible. The PCM-produced component interacts with a concentrated area of the data set. In the PCM technique, every cluster is independent of every other cluster. Reduce the goal function to a minimum:

$$J_{PCM} = \sum_{i=1}^{c}\sum_{j=1}^{n} u_{ij} d_{ij}^2 + \sum_{i=1}^{c} \eta_i \sum_{j=1}^{n}(1 - u_{ij})^m \qquad (1)$$

where η_i result in ith cluster's scales and are positive values. The values of first terms, distances between data points need to be very low while second terms force uij's values to be greater where U fulfills:

$$u_{ij} \epsilon [0,1], \quad \forall_i \ and \ j \qquad (2)$$
$$0 < \sum_{j=1}^{n} u_{ij} < n, \ \forall_i \qquad (3)$$

It is recommended to select η_i as:

$$\eta_i = \frac{\sum_{j=1}^{n} u_{ij}^m d_{ij}^2}{\sum_{j=1}^{n} u_{ij}^m} \qquad for \ 1 \le i \le c \qquad (4)$$

d_{ij}^2 represents the sample xj's possibilistic typicality value, which belongs to cluster i. The possibilistic parameter, $m \in [1, \infty)$ represents weights where the algorithm used is detailed as below:

Step 1: Assuming data objects X, fix $\in$, c, 2≤c≤n, m>1, η>1 and initialize membership function values

Step 2: Calculate centers of clusters

$$v_i^{(t)} = \frac{\sum_{j=1}^{n} u_{ij}^m x_j}{\sum_{j=1}^{n} u_{ij}^m} \quad for \ 1 \le i \le c$$

Step 3: Calculate Euclidian distances

$$(d_{ij})^2 = \|x_j - v_i\|^2 \quad for \ 1 \le i \le c; \ 1 \le j \le n$$

Step 4: Compute new satisfying

$$U_{ij}^{(t+1)} = \frac{1}{1 + \left(\frac{d_{ij}^2}{\eta_i}\right)^{\frac{1}{m-1}}} \ for \ 1 \le i \le c; \ 1 \le j \le n$$

where η_i is calculated by the Eq(4).

Step 5: If $\|U^{(t+1)} - U^{(t)}\| \le \in$, then stop; otherwise t=t+1 and return to step 2.

EFPCM concatenates possibilistic and fuzzy c-means (FCM) features [9]. Memberships and typicalities are important for accurately characterizing data substructures while clustering. Objective functions of EFPCM based on memberships and typicalities:

$$Minimize \ J_{FPCM} - \sum_{i=1}^{c}\sum_{j=1}^{n}(u_{ij}^m + t_{ij}^\eta) \ d_{ij}^2 \qquad (5)$$

with the following constraints:

$$\sum_{i=1}^{c} u_{ij} = 1, \quad for \ 1 \le j \le n$$
$$\sum_{i=1}^{c} t_{ij} = -1, \quad for \ 1 \le j \le c$$

The possibilistic algorithm based on FCM is detailed below:

Step 1: Assuming data objects X, fix $\in$, c, 2≤c≤n, m>1, η>1, 0≤u_{ij}, t_{ij}≤1 and set initial values of membership functions $U_{ij}^{(0)}$ and $t_{ij}^{(0)}$,1≤i≤c; 1≤j≤n, at step t, t=0, 1, 2, ... t_{max}

Step 2: Calculate centers of clusters

$$v_{ij}^t = \frac{\sum_{j=1}^{n}(u_{ij}^m + t_{ij}^\eta)X_j}{\sum_{j=1}^{n}(u_i^n + t_n^\eta)} \quad for \ 1 \le i \le c$$

Step 3: Calculate Euclidian distances

$$(d_{ij})^2 = \|x_j - v_i\|^2 \quad for \ 1 \le i \le c; \quad 1 \le j \le n$$

Step 4: Compute new membership values $U^{(t+1)}$ and typical values $t^{(t+1)}$ for satisfying

$$U_{ij}^{(t+1)} = \frac{1}{\sum_{k=1}^{c}\left(\frac{d_{ij}^2}{d_{ik}^2}\right)^{\frac{1}{m-1}}} \quad for \ 1 \le i \le c; 1 \le j \le n$$

$$t_{ij}^{(t+1)} = \frac{1}{\sum_{k=1}^{c}\left(\frac{d_{ij}^2}{d_{ki}^2}\right)^{\frac{1}{\eta-1}}} for \ 1 \le i \le c; 1 \le j \le n$$

Step 5: If $\|U^{(t+1)} - U^{(t)}\| \le \in$ then stop; otherwise t=t+1 and return step 2.

3.3.2. PSO

PSO is a popular optimization method that was influenced by fish schools and flocks of birds. PSO works by moving across the solution space in search of the best possible solution using a population of candidate solutions known as particles. By adjusting its location in response to both its own and its neighbors' experiences, each particle mimics a cooperative approach to problem-solving. The following is a description of the PSO's primary steps:

PSO searches for the optimal solution by utilizing a large number of particles that move in swarms within search spaces where particles are viewed as points in D-dimensional spaces, and they change their "flying" in accordance with flying experiences of particles within the swarm. To get the best answer, the particles travel in D-dimensional space at a specific speed.

The velocity of particle i expresses as $V_i = (v_{i1}, v_{i2}, ..., v_{iD})$, locations of particles i are expressed as $(x, x_{i2}, ..., x_{iD})$, while their optimal locations by $pG = (p_{g1}, p_{g2}, ..., p_{gD})$, also called p_{best}.

Global optimal positions (g_{best}) of particles are expressed as $p_g = (p_{g1}, p_{g2}, ..., p_{gD})$. Particles in groups have functions to determine fitness values. Equations (20) and (21) represent velocity updates for dimensions d in conventional PSO:

$$v_{id} = w \times v_{id} + c_1 \times rand() \times (p_{id} - x_{id}) + c_2 \times Rand() \times (p_{g_d} \quad (6)$$

$$(X_{id} = x_{id} + v_{id}) \quad (7)$$

PSO parameters include population quantities (Q), inertia weights (w), acceleration constants C1 and C2, maximum velocity (vmax), max. iterations (Gmax), and random functions rand() and rand() with values in the range of [0,1]. Typically, the values of C1 and C2 take constant 2.

PSO preserves population variety and improves information transfer across populations during optimization for overcoming constraints of traditional optimization methods in handling multi-parameters, strong coupling, and nonlinear engineering optimization issues. Among these drawbacks are the propensity to quickly enter local optimization and advanced convergence [10,11]. Parameter selections for performances are established after analyzing parameters included in imported "local-global information sharing" phrases. Global search performances of PSO are then confirmed by testing performances of PSO and classical optimization methods on classical function sets.

3.4. Classification by hyperparameter tuning Alexnet

The Hyperparameter Alexnet CNN DL architecture is suggested in the paper for medical leaf recognition. With three maximum pooling layers after five convolution layers, the network is deeper than a typical CNN. On the fully linked layers, a 0.5% dropout is applied to prevent overfitting of the data. Figure 159.2 displays the suggested design for the Alexnet CNN.

Input images are down-sampled from 640x480 to 227x227 in spatial resolution in this work's image input layer (specified as a pre-processing layer) to lower the computational cost of the DL framework. The suggested approach makes use of a Rectified Linear Unit (RELU), three pooling layers (POOL), and five convolution (CONV) layers. Ninety-six kernels with a comparatively big size of 11×11×3 are employed for the first convolution layer. A total of 256 5x5 kernels are employed for 2nd convolution layers. 384 3x3 kernels are utilized for the third, fourth, and fifth levels. The feature map produced by each convolution layer is

[12]. The first, second, and fifth convolution layer feature maps are combined with 3×3 stride pooling layers and 2 x 2 strides. The framework has 4096 nodes and an eight-layered design. In other words, feature extraction processes are carried out in these layers, producing the trainable feature maps. After applying fully connected layers (FC) to these feature maps, Soft-max activations ascertain classification probabilities that final output classification layers would employ. The Soft-max layer's classification probabilities allow for the creation of up to 1000 distinct classes.

3.4.1. Convolution network layer

These are the most important layers in DL and generate feature maps that are processed by classification layers. They include kernels that move over input images to feature maps. They perform matrix multiplications on inputs and integrate outcomes. Equation (8) defines output feature maps.

$$N_x^r = \frac{N_x^{r-1} - L_x^r}{S_x^r} + 1, N_y^r = \frac{N_y^{r-1} - L_y^r}{S_y^r} + 1 \quad (8)$$

where (N_x, N_y) represent feature map's widths and heights in last layers and (L_x, L_y) represent kernel sizes, (S_x, S_y) imply pixels skipped by kernels in horizontal and vertical directions while indices r imply layers i.e., r = 1. Convolutions are applied on input feature maps and kernels to get output feature maps defined in equation (9):

$$X_1(m,n) = (J * R)(m,n) \quad (9)$$

where $X_1(m,n)$ represents 2D feature maps obtained by convolving 2D kernels R of sizes (L_x, L_y) and input feature maps J and (*) represents convolutions between J and R depicted in equation (10):

$$X_1(m,n) = \sum_{p=-\frac{L_x}{2}}^{p=+\frac{L_x}{2}} \sum_{q=-\frac{L_y}{2}}^{q=+\frac{L_y}{2}} J(m-p, n-q)R(p,q) \quad (10)$$

The suggested system uses five CONV layers, together with a response normalization layer and a
Figure 159.2. Hyperparameter tuning alexnet convolution neural network architecture of the proposed framework.

Source: Author.

RELU layer, to extract as many feature mappings as possible from the input image in order to train the dataset as accurately as possible.

Layer of Rectified Linear Units
The network is strengthened with non-linearity in the next stage using RELU activations to trainable layers. These layers provide non-linearities which are applied to feature maps produced by convolution layers. Non-linear gradient descents are saturated for training times by tanh(.) and RELU activations where tanh(.) function can be expressed as equation (11):

$$X_2(m,n) = \tanh(X_1(m,n)) = 1 + \frac{1 - e^{-2*X_1(m,n)}}{1 + e^{-2*X_1(m,n)}} \quad (11)$$

where X_2(m, n) represents 2D output feature maps X_1(m, n) after applying tanh(.) on input feature maps is attained following passage via the convolution layer. Equation (12) shows how the values in the final feature map are acquired after using the RELU function.

$$X(m,n) = \begin{cases} 0, if\ X_2(m, n < 0) \\ X_2(m,n), if\ X_2(m, n \geq 0) \end{cases} \quad (12)$$

X(m, n) gets generated by turning negative numbers into zero and return same values in response to positive values. Since deep CNN trains quickly when RELU layers are intact, these layers are considered in the suggested architecture.

3.4.2. Maximum pooling layer

Pooling layers are incorporated after the first and second convolution layers and subsequently after the fifth convolution layers for lowering computational costs of DL frameworks. This decreases the spatial size of each image. Typically, the pooling process takes the maximum value for each image slice and averages it. Figure 159.2 shows how to apply the maximum pooling layer to the activation output in order to downsample the images.

Better results on this option are obtained when pooling is performed in the suggested work by applying the maximum value against each slice.
Figure 159.3. Maximum pooling layer.

Source: Author.

3.4.3. The Softmax activation layer and the response normalization layer

In order to lower the test error rate of the suggested network, response normalization is carried out following the first two sessions. This layer normalizes the network's overall input as well as the input layers inside networks. Equation (13), which does normalization.

$$N_{e,f}^x = \frac{b_{e,f}^x}{\left(z + \alpha \sum_{j=\max\left(0, x-\frac{C}{2}\right)}^{\min\left(T-1, x+\frac{C}{2}\right)} (b_{e,f}^x)^2\right)^Y} \quad (13)$$

where $N_{e,f}^x$ represents normalizations of neurons' activities $b_{e,f}^x$ computed at positions (e, f) using kernels k. T stands for total ranges of kernels within layers. z, c, α, and γ are fuzzy hyperparameters whose values get modified by applications of validation sets. Soft-max classifiers are used on extracted features. On performing five series of CNN layers, outputs are fed to Soft-max layers for multi class classifications that determine classification probabilities used in final classification layers for obtaining classes from images.

3.4.4. Dropout layer

In order to prevent overfitting of data, dropout layers are implemented in first two FC layers when iterations double in the network, making the neurons dense. It uses neural networks to accomplish model averaging and is a very effective method of regularizing training data. The processing of maximum pooling layers, convolution layer kernel sizes, and their skipping factors results in a downsampled output feature map of one pixel per map. The output of the uppermost layers is also coupled to a 1D feature vector via a fully connected layer. The output unit for the class label is always fully linked to the top layer, enabling the extraction of high-level characteristics from training data.

4. Results and Discussion

The study utilized data accessed from https://data.mendeley.com/datasets/hb74ynkjcn/1 for experimenting with the proposed Fuzzy Possibilistic C-Means Convolution Neural Network (HY-ALEXNET) classification methodology aimed at medicinal leaf image recognition. This algorithm was implemented using a system equipped with a 3.1 GHz GPU processor and 4 GB of internal RAM, running on the MATLAB R2021b platform. The innovative Hyperparameter tuning Alexnet approach leverages the advantages of both fuzzy and CNN to enhance the accuracy and robustness of the classification process, especially in handling uncertainty and imprecision in leaf image data. By integrating these clustering techniques with CNN, the study addresses the challenges of variability

in leaf shapes, textures, and colours, providing a more reliable classification model. The experimental results demonstrated that the Hyperparameter-Alexnet model significantly improves classification performance compared to traditional methods, highlighting its potential for practical applications in medicinal botany and related fields.

The performance metrics according to this confusion matrix are calculated as follows.

Precisions are defined as ratios of correctly found positive observations to total expected positive observations in Figure 159.3.

$$F - measure = 2 * (Recall * Precision)/(Recall + Precision) \quad (14)$$

Sensitivities or Recalls are defined ratios of correctly identified positive observations to total observations.

$$Precision = TP/(TP + FP) \quad (15)$$

F – measures are weighed averages of Precisions and Recalls and hence consider false positives and false negatives.

$$Accuracy = (TP + FP)/(TP + TN + FP + FN) \quad (16)$$

Accuracy is calculated in terms of positives and negatives as follows:

$$Recall = TP/(TP + FN) \quad (17)$$

Where TP- True Positive, FP-False Positive, TN-True Negative, FN- False Negative.

Figure 159.4 presents the results of a precision comparison between the suggested HY-Alexnet and the current approaches, demonstrating that the HY-Alexnet offers better accuracy in the classification of images of medicinal leaves. According to the results, the rule sets produced by the suggested model enable the HY-Alexnet to perform noticeably better than conventional machine learning (ML) methods, resulting in greater accuracy rates.
Figure 159.4. Comparative results for precision in medicinal leaf image classifications between suggested and existing methods.
Source: Author.

Figure 159.5. Comparative results for reacll in medicinal leaf image classifications between suggested and existing methods.

Source: Author.

The memory comparison results between the suggested and current methods for identifying the images of medicinal leaves are shown in Figure 159.5. The optimal segmentation result is obtained from the suggested segmentation model. As a consequence, the suggested HY-Alexnet models were used for the assigned work, and the outcomes were examined and assessed.

The F-measure comparison findings between the suggested and current methods for identifying the leaf images are shown in Figure 159.6. Furthermore, employing clustering techniques results in a significant reduction in the amount of time needed to complete a forecast. When compared to the other deep-learning
Figure 159.6. Comparative results for f-measure in medicinal leaf image classifications between suggested and existing methods.

Figure 159.7. Accuracy comparison results between suggested and existing methods for classifying medeicinal leaf images.

Source: Author.

models, the suggested model has the greatest f-measure rate measurement in the database, as can be seen from the comparison above. When compared to other approaches, the database that was employed yielded the best f-measure findings.

The accuracy comparison between the suggested and current methods for identifying the leaf images is shown in Figure 159.7. A deep learning model is considered successful when it can accurately predict the goal and generalize predictions to new examples. Usually, accuracy—which has two subtypes: sensitivity and specificity—can be used to gauge the validity of a model. According to the simulation findings, the suggested HY-Alexnet model has a high accuracy of 95.67%, whereas the SVM model and the current CNN model have respective accuracy of 71.41% and 93.9%. According to the findings, the suggested HY-Alexnet strategy outperforms the current classification methods in terms of accuracy.

5. Conclusion

This study effectively addresses the intricate challenge of accurately identifying medicinal plants by developing an automatic recognition model utilizing HY-AlexNet. The model classifies medicinal plant leaves into healthy and diseased categories, thereby enhancing the traditional medical system. Disease-detected images of medicinal plants are first segmented using the EEFPCM clustering algorithm, with parameters optimized by PSO. Subsequently, a CNN classifier extracts feature maps from the images. The DL model, featuring a hyperparameter-tuned fuzzy-based Alexnet blocks for feature extractions and classifier blocks for categorizing extracted features, demonstrates significant improvement in performance metrics, including accuracy, precision, sensitivity, and F-measure. These results underscore the model's capability to reliably and efficiently classify medicinal plant leaves, presenting a robust tool for advancing traditional medicinal practices through modern technological integration. Future work will cover more varieties of medicinal plant species for enhancing the model's generalizations. Advanced optimization techniques like genetic algorithms and neural architecture search (NAS) will be explored to enhance clustering and classification performance. Additionally, developing more sophisticated image pre-processing methods to handle variations in lighting and imaging conditions will be pursued.

160 Analyzing the performance of the three-phase inverter using SVPWM technique

Yogendra Kumar

Department of Electrical Engineering, GLA University, Mathura, India

Abstract: Because of this, the majority of three-phase, two-level inverters generate harmonics, which change waveforms and impact electrical loads. Pulse width modulation is a commonly used technology for semiconductor switch control. Pulse-width modulation (PWM) technologies are employed in many industrial applications where high performance is required. Third Harmonic PWM (THPWM), 60-Degree Pulse-Width Modulation (SDPWM), and Sinusoidal PWM (SPWM) are the three most popular and extensively utilized pulse width modulation algorithms. It was anticipated that space-vector pulse-width modulation would result in output that was higher-quality and had less total harmonic distortion (THD). MATLAB/Simulink is used to model the same planned system.

Keywords: Space vector pulse width modulation method, MATLAB/Simulink, three-phase inverter, control system, driver circuit etc

1. Introduction

An electrical device known as an inverter has the ability to change a DC current into an AC current at a given voltage and frequency. The inverter will use 230V AC if we want to deliver power to a household gadget at that moment. In some situations, we can utilize a 12V inverter as a power source if the power supply to household equipment is cut off. In solar structures, inverters are used to deliver electricity to appliances mounted in remote homes, boats, camper vans, and mountain cabins.

Converting DC electricity to AC voltage is the basic function of an inverter. An inverter may be made to provide the necessary output voltage by employing its switching mechanism. Usually, the pulse width modulation (PWM) method does this. Three-phase inverters employ four different PWM techniques: Space Vector PWM (SVPWM), Sinusoidal PWM (SPWM), Third-Harmonic Injected PWM (THPWM), and Sixty Degree PWM (SDPWM). A simple poll comparing the performance of SVPWM and SPWM has been carried out to determine which method performs better. According to an analysis of many PWM methods, SVPWM provides the best performance, the lowest THD, and a well-suited flexible output.

1.1. Specification of the inverter

Input voltage = 420V
Output voltage = 280v

Switching frequency = 1 kHz to 2 kHz
Current = 4.2amps.

2. Hardware Description

2.1. Block diagram

The block diagram of the overall control diagram of the special basic inverter system, which consists of a three-phase inverter, dc rectifier, controller, and load, is shown in Figure 160.1.

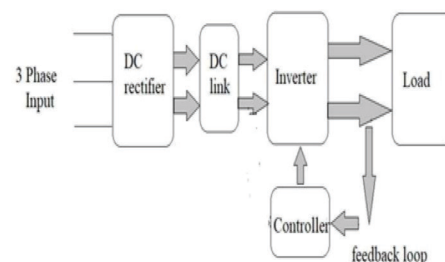
As compared to the ZSI inverter, the QZS inverter has a higher voltage inversion capacity. A QZS inverter with the same voltage gain as a normal ZSI lowers the current through inductors and the voltage stress on capacitors. QZS inverters are chosen over ZSIs due to the current discontinuity problem that is inherent in


Figure 160.1. Block diagram of the-special basic inverter system.

Source: Author.

the more common ZSI circuit configuration [8]. The components of a QZS inverter experience far less voltage stress than those of a conventional ZSI inverter.

The rectifier receives a three-phase supply in order to convert its AC supply into a DC supply. The dc link capacitor receives this dc in turn, converting it from ripple voltage to steady DC voltage. The three phase inverter receives this DC voltage in turn.

2.2. Controller system

According to the needs of the system, the controller was a device that controlled voltage and frequency. Figure 160.2 displays the hardware block diagram for the controlling component.

In order to convert and control the power to DC, a step-down transformer with a voltage ratio of 230/12 V, 1A, 50Hz was employed, using a single phase AC voltage of 230V, 50Hz. The voltage was changed from 12V ac to 12V dc using a diode rectifier. The 5V and 12V voltage regulators received this rectified direct current voltage. The Arduino microcontroller receives the regulated 5V supply and uses it to create pulses in accordance with the control strategy. The driver circuit was given a 12V regulated DC supply so that it could operate the Power Electronic switches of the suggested inverter in accordance with the gate pulses produced by the controller.

3. Methodology

3.1. SVPWM

To bring out its switching command signals and adapt them to its three-phase inverter, the SVPWM approach was previously possessed. Pre-owned SVPWM inverter offering 15% increase in dc link voltage consumption and reduced output harmonic distortions compared to typical sinusoidal PWM inverter.

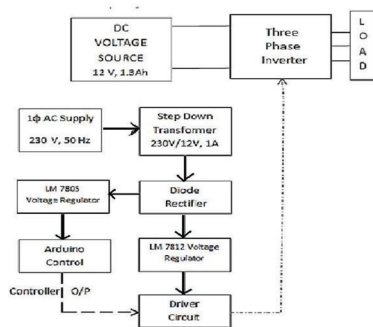
Using a three-phase inverter, the particular Principle of SVPWM was primarily demonstrated using the space vector approach. The six power switches on it were S1 through S6, namely from its output, which is made up of its switching variables a, a', b, b', and c, c'. While its


Figure 160.2. Hardware block diagram of controller part.

Source: Author.

equivalent of a', b', or c' is zero, all top transistors are activated. In light of this, all of its top switches—S1, S3, and S5—are pre-owned in order to determine its SVPWM, which refers to a certain switching configuration of its top power switches of a three-phase power inverter.

The SVPWM method was very favored compared with conventional method due to its extraordinary characteristics'.

- It uses the DC supply voltage more efficiently
- It gives more additional voltage than conventional modulation

The space vector (SVPWM) technique was an additional strategy for increasing the output voltage of the SPWM method. In comparison to SPWM, the SVPWM approach brings its fundamental element closer to 27.39%. The modulation index is increased to 1 and the fundamental voltage is raised to a square wave mode.

3.2. Three-phase inverter

The below Figure 160.3 Shows the three phase inverter.

3.3. Space vector for all combinations

The below shown Table 160.1 shows space vector switching states and resultant space vector for all combination.
Figure 160.3. Three phase inverter.

Accomplishment of Space Vector PWM
- Step 1. Determine its direct axis and quadratic axis voltage Vd, Vq, Vref, and its angle (a)
- Step 2. Determine its time duration T1, T2, T0
- Step 3. Determine its switching time of all transistor (S1 to S6)

4. Results and Discussions

The three-phase inverter simulation circuit using the SVPWM approach is displayed in Figure 160.4. This uses a sine function block to construct the voltage reference waveforms for the three phases and provides them for the Clarke transformation. In order to create the pulses for the inverter, the svpwm block needs the converted voltage.

The voltage measurement blocks are utilized to get the measured voltage and, with the aid of the scope block, show it as waveforms. The output of these RMS blocks, which transform a peak value into an RMS value, is sent to the scope for waveform viewing.

For modulation index=1 and switching frequency =1 kHz

Peak to peak voltage:

Y – axis: Voltage(V)   X – axis: time(sec)

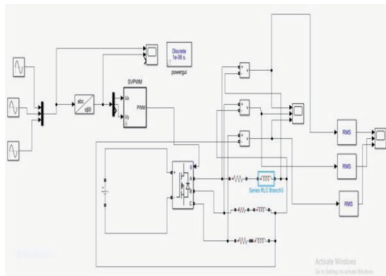
The three-phase system is transformed to a dq plane of reference by providing the control block with reference signals that have a peak-to-peak voltage of 560V. The waveforms for a 0.5-second time period are displayed in Figure 160.5.


Figure 160.4. Simulation model for three phase inverter.
Source: Author.

Figure 160.5. The dq plane of reference for three phase inverter.

Source: Author.

The three phase load voltage waveforms are provided below:

Y – axis: Voltage(V)   X – axis: time(sec)

It is evident that there is a 120-degree angle of displacement between the three phases. For a frequency of 50Hz, a peak-to-peak voltage of 560V may also be seen in each phase. The rms

Y – axis: Voltage(V)   X – axis: time(sec)

With m=1 and a switching frequency of 1 kHz, the load voltage's root mean square value equals around 170V in Figure 160.12.

The recommended operating conditions for this inverter are 50 Hz, RL load type, and 0.8 power factor. The necessary inputs for running the model and displays the outcomes of the simulation in Figure 160.6.
Figure 160.6. Three phase load voltage waveform for phase a.

Figure 160.10. Simulation result for m = 1 and fs = 1 kHz.

Source: Author.
Figure 160.11. Simulation result for m = 1 and fs = 2 kHz.

Source: Author.
Figure 160.12. Simulation result for m = 0.8 and fs = 2 kHz.

Source: Author.

5. Conclusion

Table 160.2 shows the THD of the SVPWM inverter for various modulation indices and switching frequencies. It is shown that a significant reduction in THD occurs with increasing switching frequency.

Table 160.2. Variation of switching frequency with modulation index

Modulation index	Switching frequency	SVPWM (THD)
0.8	1 kHz	25.88%
0.8	2 kHz	4.40%
1	1kHz	25.87%
1	2 kHz	4.39%

Source: Author.

In conclusion, the use of pulse width modulation (PWM) technologies—such as 60-Degree Pulse-Width Modulation (SDPWM), Third Harmonic PWM (THPWM), and Sinusoidal PWM (SPWM)—is essential for reducing harmonics and enhancing the efficiency of three-phase, two-level inverters in industrial settings. Higher-quality output with lower total harmonic distortion (THD) is predicted to be achievable with the use of various PWM techniques, especially space-vector pulse-width modulation. Engineers are able to maximize the performance of power electronic systems for a range of electrical loads by utilizing MATLAB/Simulink to simulate these kinds of systems and simplify the analysis and design process. Therefore, PWM technology is essential to raising the effectiveness and dependability of contemporary power conversion systems.

161 Enhanced data security and privacy in healthcare using a new secentralized blockchain architecture

Yogendra Kumar

Department of Electrical Engineering, GLA University, Mathura, India

Abstract: This paper presents a novel decentralized blockchain architecture to solve the pressing demand for improved data security and privacy in the healthcare industry. The suggested design takes advantage of blockchain's built-in benefits of immutability, transparency, and auditability while using a clustering technique to reduce computation costs and communication overhead. Strong access control and data integrity are also guaranteed by this resource-efficient method. Our results show that the suggested approach provides robust defense against prevalent security risks in the healthcare sector. Our design yields a 10x decrease in network traffic and a 63% improvement in ledger update time when compared to lightweight blockchain systems and current blockchain, demonstrating its better performance and usefulness for healthcare applications. In spite of these noteworthy developments, further investigation is required to include this architecture with the existing healthcare IT infrastructure, determine whether it is appropriate for certain healthcare situations, and carry out comprehensive testing to determine its practical efficacy. The scalable, transparent, and secure solution that this novel blockchain architecture offers will ultimately enable healthcare organizations to safeguard patient information, uphold confidence, and create a more resilient healthcare ecosystem.

Keywords: Blockchain, healthcare, privacy, data security, cyberattacks, decentralized architecture, clustering

1. Introduction

The healthcare industry stores a tonne of sensitive data, including financial and medical information. The fact that cyberattacks against healthcare companies are becoming more frequent and sophisticated is evidence that this unsung treasure attracts unwelcome attention. These attacks compromise patient privacy, result in significant financial losses, and disrupt essential operations. Robust data security and privacy protections are increasingly essential for guaranteeing the security of our healthcare systems and the individuals they serve. The foundation for this study's innovative approach to healthcare data security is a decentralized blockchain architecture. Our concept tackles the two primary barriers to the widespread use of blockchain technology in the healthcare industry: communication overhead and computing cost. The inherent properties of blockchain technology include auditability, transparency, and immutability.

In a similar vein, blockchain is already receiving a lot of attention and has the potential to completely transform the current framework of technologies connected by the Internet. It is a distributed, decentralized public ledger, administered by a collection of computers, and a time-stamped sequence of immutable data entries that are not held by a single entity. Therefore, the combination of these two highly regarded and practical technologies can benefit a number of businesses and institutions.

One significant area where blockchain technology is being applied is in the healthcare sector, where it is bringing about dramatic changes in conventional diagnostic procedures to current diagnostics systems based on patient history. Imagine a situation in which the doctor may check the patient's prior medical history, current medical conditions, and prescription medications from other hospitals before recommending a course of therapy. The best course of action may be determined and recommended in such a situation. Furthermore, such a dramatic shift can also benefit the national economy. When providing such essential information, user trust is a big and significant element. Patients will come to distrust electronic health

care systems if there is any delay in sharing. There is a ton of work to be done in a safe healthcare system, but certain issues, such higher return traffic and mild management of known risks, point to areas for further research. In this case, using blockchain technology in healthcare may be a better way to protect against known dangers and lessen the volume of rising traffic.

Our biggest contribution is the way we group network users into clusters and keep different blockchain copies for every cluster. This method maintains data integrity and access control while drastically cutting down on resource usage. This translates into reduced expenses, faster transactions, and more scalability, which makes our design very appealing for the resource-constrained healthcare setting. Beyond theoretic benefits, we show how our design efficiently counteracts a variety of cyberattacks that are common in the healthcare sector. In order to demonstrate our design's improved performance and appropriateness for practical healthcare applications, we also compare it to other blockchains and lightweight blockchain architectures. The vital problem of healthcare data security is effectively and practically solved by the study. We provide a safe, transparent, and scalable architecture that can preserve patient privacy, guarantee data integrity, and defend our healthcare systems from cyberattacks by creatively and effectively utilizing the promise of blockchain technology.

2. Related Work

In recent years, a number of scholars have addressed and voiced concerns regarding data-sharing and medical records. [26] introduced the concept of the fully functional MedRec blockchain prototype, which handles medical records. The challenges and restrictions of using blockchain technology into electronic health record systems were covered in [17, 27]. These included issues with performance and scalability, secure and authorized identification, lack of incentives, and excessive and insufficient use. [5] provided a survey on patient data management that examines the self-sovereign component using blockchain. [29] investigated and carried out a study on the application sector of blockchain in the healthcare industry using a blockchain methodology. A complete architecture for IoT devices has been provided, based on revised blockchain models [30]. The authors of [31] have proposed a prudent application of blockchain technology and IoT integration for integrated autonomous sewage management systems. Many of the existing blockchain techniques may view and reference the framework and model.

This hybrid paradigm combines the benefits of blockchain, public key cryptography, and private key technology. Because they often do not interface with other systems [33] and exchange health and medical records internally [32], legacy systems are crucial to the healthcare industry. Combining these two paradigms has several advantages [16], including better and more integrated healthcare services. A privacy-preserving approach for advanced obstinate threads has been developed for a cyber-physical system [34–37]. Here, the authors use an index level of privacy to calculate the differences between the transmitted and original data in order to verify the degree of data privacy maintained.

In Internet of Things healthcare systems, resource limits provide a difficulty that is addressed by a secrecy architecture known as homochain-based security [38]. According to the authors, in a blockchain network [39], the average order of time complexity increases exponentially with node count, whereas in a homochain, the average order of time complexity remains constant as node count increases.

Another crucial issue is data sharing across organizations, which requires that the health and medical information produced by one member of the healthcare staff be securely shared with other entities that want healthcare, such a physician or a healthcare research institution [40, 41]. It summarizes the numerous blockchain-based applications in the healthcare industry.

2.1. Research gap in current solution and motivation

Due to a significant weakness in the current system—that is, the fact that healthcare data is stored in centralized databases in layers—it would become an extremely attractive target for cybercriminals. Numerous studies have shown that centralization increases the risk of cyberattacks and demands trust in a single authority. Another issue that requires careful attention is the possibility of the record being permanently erased. The majority of EMRs are really stored in centralized databases under the present approach, which increases the security risk perimeter and calls for a dependence on single authority that is insufficient to protect data from insider threats. That's the premise underlying this remedy that has been presented.

3. Proposed Technique

The decentralized currency of bitcoin, which is supported by a peer-to-peer network technology, was first utilized. Every transaction in this is visible to the whole network, and every miner that receives it can confirm or validate it using their signatures included in the transaction. These miners also include this validated

transaction at the end of their own block. This demonstrates how the blockchain verifies a single transaction using many miners, demonstrating the resolution of the transaction. Figure 161.4 depicts the data flow diagram for the suggested architecture, and Figure 161.4 shows the suggested architecture for secure healthcare data management based on blockchain technology. It illustrates the principal elements of architecture along with their relationships and purposes.

3.1. Participant nodes

Using analytical calculations, the optimal geometric dimensions for the sensor with concentric electrodes were discovered [37]. Using Equation (1) and its mathematical relationship, the sensor response function was found to be:

Any entity chosen to join the network has an equal influence on the network, as shown in Figure, and in a decentralized design, each entity exchanges a copy of the activity data as a ledger in Figure 161.1. With a distributed ledger and the blockchain, databases may be exchanged directly between parties without the need for a middleman. The transactions are processed and stored by the network nodes. Upon reaching a consensus, the nodes refresh the ledger in Figure 161.2.

The transaction data of the blockchain network are replicated on the network nodes in a manner that starts with the first transaction and works backwards toward all subsequent transactions in Figure 161.3. Since modifications to the infrastructure are instantly apparent, they are transparent and safe.

In the blockchain, transactions are stored in blocks. Every block in the series chain is connected to the block before it using a safe hash function in cryptography in

Figure 161.4. Any effort to change the text of a block will impact the blocks in the series chain that follow it. An adversary with malicious intent would thus need to computationally modify every subsequent block in the chain in order to update a single block. Because the duplicate copy of the linked blocks is spread over several nodes, this becomes very difficult to change. As a result, the recommended design is safer.

In every scenario, the bitcoin network uses a linear growth in the quantity of data it uses, which raises processing overheads and traffic. Overall, the total amount of data sent using the novel approach that has been proposed is frequently 13 times less than that of the traditional bitcoin network and 3 times less than that of the LW blockchain technology.

Figure in the proposed architecture illustrates the entire processing time and restoration time for ledger updates at each secure medical data center and secure network node independently. In comparison to the LW blockchain and the conventional bitcoin network, the total amount of data exchanged and sent is ten times less than when the number of nodes increases. Using a safe hashing method on sensitive medical information, we assess the efficacy of our proposed decentralized architecture in terms of security and privacy accuracy. The testing findings are displayed in Figures 161.5 and 161.6, where our suggested approach guarantees great accuracy when compared to the LW blockchain and bitcoin.

The network throughput was then examined in Figure for various participant combinations. About operational performance, here, found that most scheduling nodes had a large influence, while network delay had a moderate effect on delegates, contributors, and

administrators. Furthermore, we found that up to 20 transactions could be finished with the lowest burden.

4. Conclusions

In order to meet the pressing demand for improved data security and privacy in the healthcare sector, this article has proposed a revolutionary decentralized blockchain architecture. Our architecture uses a clustering approach to handle the issues of computing cost and communication overhead, while also using the inherent benefits of blockchain technology, such as immutability, transparency, and auditability. In addition to conserving resources, its approach upholds access control and data integrity. The findings of our study indicate that the suggested design provides robust defense against several assaults that are frequently faced in the healthcare industry. this approach has demonstrated its improved performance and applicability for practical healthcare applications by being compared to existing blockchain and lightweight blockchain systems. Further confirming its promise to transform healthcare data management are the 10x decrease in network traffic and the 63% quicker ledger updates.

Even though this discovery is a major advancement, more investigation and advancement are required. Subsequent research endeavours may delve into the assimilation of our architectural design with extant healthcare information technology infrastructure, examine its suitability for certain healthcare scenarios, and execute extensive trial runs to evaluate its practical efficacy. In the end, I think there is a lot of potential for this unique blockchain architecture to change healthcare data security and privacy. By offering a scalable, transparent, and secure solution, we can enable healthcare organizations to safeguard patient information, uphold confidence, and create a more robust healthcare ecosystem.

162 Study of THD reduction in voltage source inverter with PI controller against variation in loads and unexpected input

Yogendra Kumar

Department of Electrical Engineering, GLA University, Mathura, India

Abstract: This work investigates harmonic mitigation in a full bridge voltage-fed sine wave inverter connected to a load with a unity power factor. The state space model of the voltage source full bridge sine wave inverter was developed by taking into account its switching sequence. The controller lowers the overall harmonics of the inverter by selecting the best PI constants. It was discovered that even in the face of an abrupt rise in input and load changes, the PI algorithm dramatically lowers the harmonic levels. MATLAB/Simulink was used to examine this harmonic reduction strategy.

Keywords: Voltage source inverter, PI controller, total harmonic distortion

1. Introduction

Power electronic converter circuits are the main cause of harmonics in electrical power circuits. Within this particular context, the term "inverters" pertains to devices that convert direct current (DC) into alternating current (AC). An inverter converts a direct current (dc) input voltage into a symmetrical, correctly sized, and appropriately frequented alternating current (a.c.) voltage. Inverters employ pulse width modulation (PWM) techniques to produce a low-distorted sine wave, which is suitable for high-power applications. VSIs, also known as inverters with voltage sources, are a type of power electronic converter commonly used for nonlinear loads. Power frequency harmonics are generated during the process of inversion. A harmonic voltage or current is characterized by having a frequency that is a whole number multiple of the fundamental power frequency. When voltage and current waveforms deviate from sinusoidal patterns because of non-linear loads, the term "harmonic distortion" is frequently employed. Harmonic inverters can lead to power loss, distortion, interference, and overheating when subjected to heavy loads.

This article explains how to use the proportional-integral (PI) controller to reduce harmonics in a full bridge voltage source sine inverter. Numerous combinatorial optimization issues, such as the traveling salesman problem and optimal structure designs, may be resolved with the Bat approach [1]. Using this technique, data is taken from optical cluster samples [2]. The efficiency of the algorithm may be increased by hybridization. It is recommended to apply a unique hybrid Bat algorithm (BA) based on the differential evolution (DE) method, which is more successful than previous strategies [3]. Power outages are a major problem for the electric distribution sector. The Bat method [4] can be used to determine the ideal system design with the lowest loss rate. Single-phase dc-ac inverters can have selected harmonics eliminated when they are operated at ideal switching angles. To estimate these switching angles, a set of nonlinear equations based on the secant technique are solved [5]. Lower-order harmonics can be eliminated using a complete bridge inverter based on square-wave MOSFETs [6]. It is possible to eliminate harmonics using a variety of modulation techniques [7]. It is possible to lower the inverter dead time and zero voltage transition period harmonics [8–9]. This paper suggests a hybridization of the Bat approach with a PI controller. Crossover and mutation are two genetic algorithm processes that may be used with BA to improve performance [10].

Multilevel inverters exhibit a significant reduction in harmonics compared to single-phase inverters, as demonstrated by the MATLAB simulation result [11]. To handle global numerical optimization across continuous domains, an enhanced version of the Self-Adaptive Bat Algorithm is employed [12]. Electrical contamination and equipment malfunction may arise from improper handling of harmonic reduction in VSI.

2. Proposed Stategy

The switching technique modifies the frequency of the output alternating current waveform. Enhancing the amplitude of the output voltage can be achieved by directly modifying the amplitude of the source voltage. Understanding the function of the steady-state inverter can be achieved by considering two modes of the circuit and a control variable u that belongs to the set {0, 1}. A proposed mathematical model describes a voltage-controlled single-phase complete bridge inverter. The model is based on bipolar voltage switching using SPWM. According to prevailing belief, each component is considered to be optimal. An alternating voltage is produced by closing switches S1 and S2 for half of the switching duration, while keeping switches S3 and S4 open. S1 and S2 are open during the second half of the session, whereas S3 and S4 are closed.

The control variable 'u' is defined as:

$$u(\theta) = \begin{cases} 0, -\propto < \theta < \propto \\ 1, \propto < \theta < \alpha \end{cases}$$

u = 1 if switches S1 and S2 are on. u = 0 if switches S3 and S4 are on in which the variable u is a control.

3. Modeling Analysis of VSI Using PI Controller

Figure 162.2 displays the Simulink block diagram for reducing the total harmonics in a single phase full bridge sine wave VSI with a PI controller. Generally, a low-distorted sine wave inverter is favored in high-power situations. Using a PI controller, the full-bridge VSI for harmonic reduction is simulated using the MATLAB/SIMULINK tool in Figure 162.1. By
Figure 162.1. Voltage source inverter circuit schematic for a single phase full bridge.

Source: Author.
Figure 162.2. THD reductions in single phase VSI utilizing PI controller: Simulink block diagram.

Source: Author.

comparing the actual output signal with the reference sine wave, a control signal is produced by the traditional PI controller. The inverter switching is adjusted using this control signal. The technique of sinusoidal PWM is utilized in order to decrease the overall harmonic distortion. To reduce the amount of THD, the LC filter section receives additional feeds from the inverter output.

4. Result and Discussion

The simulation results of VSI using a PI controller were obtained using the software MATLAB 2010B. The following are the advantages of using MATLAB [16].
- Faster response in Figure 162.2.
- Availability of various simulation tools and functional blocks.
  Absence of convergence problems.

4.1. Harmonic spectrum of VSI using PI controller

The output voltage and current harmonic spectra of a full bridge voltage source inverter that makes use of a PI controller are shown in Figures 162.3(a) and (b). It is observed that when harmonic order n increases, harmonics decrease by a factor of 1/n.

Using a PI controller, the output voltage and current of the VSI are subjected to a rapid fluctuation in the load resistance in Figure 162.2.

Figure 162.5 shows that under various operating circumstances, the voltage THD remains constant in magnitude in Figure 162.3. Additionally, a little rise in the voltage THD magnitude is seen for fluctuations in the input voltage and output load. Both load fluctuations and a sudden increase in input cause an increase in the current THD magnitude in Figure 162.4. Overall, the finding verified that while current harmonics are load dependent, voltage harmonics are reliant on source stability and network impedance. Furthermore, under various operating situations, the current

Source: Author.

Figure 162.5. Voltage and current THD's for different operating conditions using PI controller.

Source: Author.

distortion factor fluctuates, while the voltage distortion factor remains constant in magnitude.

5. Conclusions

This work discusses the fundamental methods used to reduce the total harmonic distortion (THD) of the full bridge voltage source inverter, as well as the general background, features, and disadvantages of the PI controller, as well as the representation of the PI controller block diagram in Simulink and the simulation response curves it produces. An automatically adjusted PI controller is used to accomplish the THD magnitude, which is somewhat less than what IEEE standard 519-1992 recommends. It is discovered that consistent voltage harmonics lead to decreased current harmonics, improved power factor, reduced power losses, and ultimately higher efficiency.

163 A prototype of solar powered smart dustbin

Arti Badhoutiya

Department of Electrical Engineering, GLA University, Mathura, Uttar Pradesh, India

Abstract: A technologically advanced waste management system, the advanced smart dustbin is intended to increase user convenience, efficiency, and hygiene. It employs weight and ultrasonic sensors for precise fill-level monitoring with timely alarms, and sensor-based lid automation for hands-free operation. The bin uses AI-driven smart sorting to separate recyclables, biodegradable garbage, and landfill waste. It also has an automatic compaction mechanism to maximise waste volume. Deodorisers and firmly closed lids help control odour, and GPS tracking, IoT integration, and mobile apps make it easier to connect. Effective battery management and solar panelling provide energy efficiency. Voice control and a touchscreen interface simplify user engagement, while locking mechanisms and security cameras improve security. Contactless operation and UV light sanitisation are additional health and safety advantages. In addition to collecting environmental data, the smart dustbin facilitates user feedback, so offering itself as a holistic solution for contemporary waste management requirements. The article explains how trash management has improved thanks to technology, creating a better, cleaner environment.

1. Introduction

There is one terrible issue that needs to be addressed while the planet upgrades. We frequently see images of trash cans being overfilled to the point that everything spills out. Due to the enormous number of insects and mosquitoes that nest there, this increases the number of diseases. Solid waste management is a major issue in urban areas, not just in India but in the majority of other nations as well. Therefore, a solution that can either completely eliminate or drastically lessen this issue needs to be built. The initiative provides us with one of the most effective means of maintaining a clean and green environment [1]. To assist solid waste management authorities in raising the calibre of service delivery, a number of waste management solutions with IoT capabilities have been developed and put forth in the literature. Researchers combined two distinct wireless technologies to create a robust management system that employs WSN. As a sensor node, Waspmote has been employed. The ATmega1281 microprocessor in the mote has an integrated accelerometer sensor. At the sensor node, many types of sensors are applied, including level, weight, humidity, and temperature sensors. Some studies take advantage of RFID technology to boost waste management effectiveness, particularly when it comes to tracking waste collection operations. Additionally, it could lighten the truck driver's burden when it comes to

documenting the collecting procedure and the surrounding environment [2]. In addition, waste that has been dispersed around the dustbin is also tracked using an infrared sensor to preserve the city's hygienic conditions. Wastes are divided into two categories: solid trash and liquid waste. Both types of garbage are hazardous. Additional categories for it include hazardous waste, e-waste, organic garbage, medical waste, recyclable waste, and reusable waste. Residential, commercial, and industrial regions are the three main producers of the liquid waste.

Examples include residential discharges and contaminated industrial water. Solid garbage is made up of things like food scraps, old furniture, metal and tin scarps, etc. In India, workers arrive every two to three days to collect rubbish from dumpsters; however, when the dustbins are full of dust, there is no way to empty them [3]. It results in waste spills, which lead to an unclean atmosphere and a host of illnesses. It is brought on by the government's lack of resources to determine whether the dustbin is full before the designated day for waste collection. Given how quickly the population is growing, the waste collection model or strategy that is currently in place is inadequate. The majority of bacterial and viral illnesses arise in contaminated environments. Technology-based environmental protection is currently required. The majority of the public space appears to be contaminated with rubbish. Thus, it is necessary to modernise restaurants by

implementing smart technology. Two primary elements influence trash amounts in any particular area: the population and its consumption patterns [4].

2. Technological Features in the Proposed Solar Power Dustbin

By integrating various features, the smart dustbin enhances convenience, hygiene, and efficiency in waste management, contributing to a cleaner and more sustainable environment:

1. Approach Detection: The motion or proximity sensor detects a user's approach, triggering the lid to open automatically.
2. Waste Disposal: The user disposes of the waste, which may be sorted automatically into different compartments.
3. Compaction and Odor Control: The waste is periodically compacted to increase capacity, and deodorizers or sealed lids manage odors.
4. Fill-Level and Maintenance Alerts: Sensors monitor the fill level and send alerts when the bin is nearly full or if maintenance is required.
5. Data and Connectivity: The bin's status, including fill level, battery life, and environmental data, is communicated to a central system or mobile app.

Electronic components such as an Arduino, Servo motor, ultrasonic sensor, and GSM module are used in Smart Dustbins [5]. In this, the Arduino and GSM modules are interfaced to provide code for opening dustbin lids and delivering notifications to mobile devices. When compared to the dustbins mentioned above, this smart dustbin is more effective and efficient. This is how this clever trash can operates: The ultrasonic sensor is located on the front side of the trash can and is connected to both Arduino and the dust can lid. When a hand and garbage are placed in front of the ultrasonic sensor, the dustbin's lid opens, allowing the rubbish to be placed within. The sensor is designed to identify human hands and waste. Another ultrasonic sensor is located within the trash can where it measures the height of the waste material inside. This distance is used to send a notice via a GSM module to a mobile device, indicating whether or not the trash can is full. The features in the smart bin are depicted in Figure 163.1.

Artificial intelligence (AI) algorithms applied to sensor-based sorting procedures greatly improve trash sorting systems' accuracy and efficiency by automating and optimising the identification and separation of various materials [6]. These systems use a variety of sensors, including optical, X-ray transmission, and near-infrared (NIR) sensors, to identify and categorise materials according to their physical characteristics, including as size, colour, and composition density. Artificial intelligence (AI) algorithms evaluate the information gathered from these sensors instantaneously, enabling accurate material identification and classification, encompassing polymers, metals, paper, and glass. Artificial intelligence

(AI)-driven sorting systems can decrease misclassification incidents and increase accuracy by continuously learning from the data and modifying their categorisation criteria.

As an outcome, recycling streams are less contaminated, recyclable materials are of greater quality, and recycling process efficiency is raised overall. Furthermore, in order to increase throughput and decrease downtime, sorting machinery like robotic arms and conveyor belts can be operated more efficiently by AI algorithms, which will increase the overall effectiveness of garbage sorting operations [7]. In order to get thorough data regarding waste objects, modern advances in sensor-based sorting entail the integration of several sensors, such as optical, infrared, and electromagnetic sensors. The data gathered by these sensors is processed by AI algorithms, which enable accurate waste item identification and categorisation. Real-time feedback mechanisms are also being added to sensor-based sorting systems to improve their efficiency. This allows for instantaneous modifications to the sorting parameters in response to the incoming waste stream. This flexibility guarantees precise and effective sorting even in the face of changing trash compositions.

The goals of these developments in AI-driven waste sorting technology are to increase precision, speed, and flexibility. Sorting garbage processes are made more effective, lower contamination, and produce higher-quality recycled materials by incorporating cutting-edge sensors, image recognition, machine vision, robots, and machine learning algorithms [8]. These AI-driven sorting devices will be essential in advancing sustainable waste management techniques and a circular economy as technology develops.

3. Operation of the Dustbin

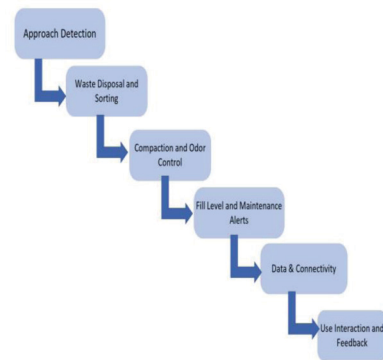
When a person approaches the dustbin, the motion sensor detects movement and triggers the lid to open automatically, providing hands-free access. Features like sensor-based lid automation and voice control reduce the need for physical contact, promoting better health and safety. Proximity sensors detect when a hand or object is close to the lid, triggering it to open. Ultrasonic Sensors


Figure 163.1. Features in a smart dustbin.

Source: Author.

installed inside the dust-bin, these sensors emit sound waves to measure the distance to the waste [9]. When the waste level reaches a certain threshold, an alert is sent to notify that the bin is almost full. Weight sensors measure the weight of the waste. Once the weight reaches a preset limit (50 Kgs), the system sends a notification indicating that the bin needs to be emptied. The dustbin has an integrated compactor that periodically compresses the waste, increasing the bin's capacity and reducing the frequency of emptying. Sensors and AI analyze the type of waste being deposited (e.g., recyclable, compostable, landfill) and direct it to the appropriate compartment within the bin. This can be achieved using image recognition technology or other identification methods [10]. The bin includes built-in air fresheners or activated charcoal filters to neutralize odors. The lid closes tightly to prevent odors from escaping, enhancing overall hygiene. The dustbin connects to the internet, allowing remote monitoring and data collection. This can help in tracking usage patterns and optimizing waste management routes. For public or large facility use, the bin's location can be monitored to ensure it remains in its designated spot. Solar panels on the bin provide power for the sensors and compaction mechanism, making it energy-efficient and reducing the need for frequent battery replacements. The system includes efficient battery usage protocols and sends alerts when the battery is low [11]. UV light sanitization inside the bin periodically kills germs and bacteria, maintaining a higher level of hygiene.

4. Conclusion

The article discusses how technology has improved waste management for a cleaner, better environment. A number of functions are included in the sophisticated smart dustbin to improve user convenience, hygiene, and waste management effectiveness. It has motion and proximity sensors for hands-free operation, sensor-based lid automation, and fill-level monitoring with weight and ultrasonic sensors to notify users when the container is full in Figure 163.2. Waste is periodically compressed by an automatic compaction device, which increases capacity. Recycling, compostables, and landfill trash are separated using smart sorting capabilities that leverage sensors and
AI. Sealed lids and integrated deodorisers help control odour. GPS tracking, an IoT integration, and a mobile app for remote monitoring and control are examples of connectivity features. The use of solar panels and effective battery management leads to energy efficiency. Locks and security cameras improve security while voice control and a touchscreen interface make it easier for users to connect with the system. UV light sanitisation and hands-free operation put health and safety first. In addition, the trashcan gathers environmental data, including temperature and air quality, and it has an interface or app that lets users leave comments. While many smart dustbins on the market now only offer basic automation and connectivity, more sophisticated capabilities are being added as technology develops.

164 Enhanced performance of photovoltaic systems with LUO converter and modified P and O tracking algorithm

Yogendra Kumar

Department of Electrical Engineering, GLA University, Mathura, India

Abstract: In order to maximize power extraction, a customized Perturb and Observe (PandO) tracker controls a unique photovoltaic (PV) system coupled with a Luo converter. By increasing the output voltage level, the suggested converter substantially reduces ripples and enables maximal power point tracking (MPPT). The results of the simulation show that, in comparison with traditional equivalents, the Luo converter improves the minimum current. Additionally, it increases the overall stability of the PV system by reducing oscillations around the MPP and guaranteeing quick and strong reactions. With its quick response to changing conditions, the updated PandO algorithm reduces energy loss. The enhanced stability, dependability, and decreased oscillations of the updated PandO algorithm in comparison to the traditional form are confirmed by experimental validation using a PV module and the Luo converter.

Keywords: Reliability, modified PandO tracker, PV system, stability improvement, grid synchronization

1. Introduction

Many nations are eager to incorporate renewable energy sources into their current power systems due to a number of factors, including the growing demand for electricity, the scarcity of fossil fuels, reliability concerns, and significant transmission and distribution losses. The frequency and phase of the output ac voltage must match the grid voltage in order for integration to occur. It is also necessary for the voltage across the inverter to exceed the grid in order for electricity to be transferred from the PV source to the grid. The output voltage magnitude of a DC buck converter, also known as a step-down converter, is always lower than the input voltage magnitude [4]. The output voltage of this switched mode power supply can be either greater or lower than the input voltage. It is known as an inverting converter because the polarity of the output voltage is the opposite of the input value. In contrast, a boost converter increases the input voltage by using the switch's duty cycle. The input voltage of a buck-boost converter is either boosted or bucked. This will enable the monitoring of grid and inverter voltages, as well as the optimization of inverter efficiency. A phase-locked loop can achieve synchronization of the output signal's phase and frequency by utilizing the grid voltage as a reference and employing a closed-loop feedback control system. This study introduces a photovoltaic (PV) system that optimizes power extraction by employing LUO converters and a modified perturb and observe (PandO) tracker. This article provides a comprehensive description of a single-phase grid-connected inverter used in residential photovoltaic (PV) systems. It covers the inverter's design, development, and assessment of its performance. The inverter is constructed using contemporary techniques for coordinating utility grids and introducing power into the device. The novel methodology employs the Root Mean Square (RMS) and adjusts the phase shift leading angle. The adjustable phase shift leading angle of the inverter alters the phase angle of the reference sinusoidal voltage in order to achieve the optimal power factor when using pulse width modulation (PWM). The Matlab software is utilized to generate this programmable phase shift leading angle.

2. Proposed Approach

The improved power factor of supply current and overall harmonic distortion are two important aspects of power quality conditioning performance that are influenced by the passive parts of the solar voltage source inverter. Figure 164.1 shows the suggested LUO

converter control technique using a modified PandO tracker.

The system comprises a synchronizing system, linked load, 80W photovoltaic (PV) module, inverter circuit with filter and step-up transformer, and LUO converter. The purpose of the inverter is to provide electricity with a voltage of 220V and frequency of 50Hz to power household loads. It is also capable of connecting to Egypt's utility grid and returning any surplus energy. The inverter is equipped with an integrated AC filter that effectively eliminates SPWM voltage harmonics, thereby enhancing power quality. The objective of this high-end inverter was to decrease the dimensions and minimize the inefficiencies of traditional AC transformers. Installing filters on the bottom side of the inverter can enhance grid performance and mitigate grid resonance. The DC capacitor filter on the DC side controls the DC-link voltage and removes AC components to optimize maximum power point tracking (MPPT), while the set serves as a connection between the inverter and the utility grid.

3. Modeling of Proposed Approach

3.1. Modeling of PV system

Direct current is produced by the PV system by employing photovoltaic semiconducting materials to convert solar energy. To generate the necessary solar energy, a photovoltaic system uses solar panels; temperature and irradiance are important factors. Temperature and irradiance fluctuations cause the PV's output voltage to vary. This study uses a high gain LUO converter to economically eliminate oscillation and increase output power. A perfect solar cell is created by connecting a current source in parallel with a diode, as seen in Figure 164.2.

3.2. Modeling of LUO converter

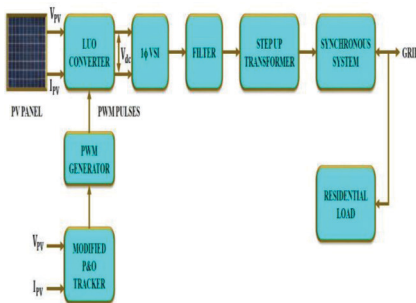
Figure 164.3 displays the Luo converter's circuit schematic. It boosts the input voltage using the voltage lift technique.


Figure 164.1. Block diagram of proposed system.

Source: Author.

3.3. Modeling of P and O algorithm

Under conditions of consistent load and weather, the conventional PandO method performs exceptionally well. Nevertheless, in situations where the weather is erratic and the load remains consistent, it performs extremely poorly. In order to maintain a consistent load and attribute any fluctuations in power to changes in weather conditions, we have made adjustments to the conventional PandO algorithm to accommodate this situation when there are sudden or gradual shifts in irradiance. This enabled us to attain enhanced performance while maintaining a consistent workload (RL). Furthermore, the program determines that the power shift is a result of the load change (ΔRL) when the weather conditions remain constant.

Modification procedure due to weather change

The load resistance (RL) in the modified PandO algorithm facilitates the identification of the power change's cause, which might be the load or the weather. Combining load change and weather approaches results in a redesigned PandO algorithm. This technique ascertains if the power fluctuation is caused by the load or the weather. The enhanced PandO algorithm's steady-state oscillations are reduced with rapid MPP monitoring. These are satisfied by the variable "d," which creates a linear connection between the voltages at the input and output. This setting significantly affects the
Figure 164.2. PV system.

Source: Author.
Figure 164.3. LUO converter.

Source: Author.
Figure 164.4. Modified P and O method's flow chart.

Source: Author.

duty cycle "D," which speeds up the algorithm's ability to monitor MPP. Figure 164.4 shows the flow chart for the Modified P and O algorithm.

The duty cycle met the ideal parameters for extracting MPP when it changed less at higher values of d and much at lower values of d. In a stable condition, oscillations are lessened by changing the duty cycle. Due to truncation errors, the zero value is frequently a floating point that cannot be computed in a way that is realistically close to it. The minimal change in power about its power ($\Delta P/P$) is suggested to be smaller than the valuable value to meet this condition. The duty cycle and value of "d" are fixed by the method if the change in power ($\Delta P/P$) is less than 0.005.

3.4. Modeling of 1Φ VSI and Grid

A LUO converter is used to raise the PV voltage, and a PandO tracker is used to maintain the LUO converter's output constant. In order to synchronize the resulting DC voltage with the grid, it is converted into AC using 1Ξ VSI. Figure 164.5 shows the block form of PV with grid synchronization.

3.5. Inverter synchronization

For a grid inverter to guarantee that its sinusoidal output voltage is in sync with the grid voltage at the same frequency, it needs a pure sinusoidal fundamental voltage. As per the Egyptian network code, the inverter's utility grid connection can only be fulfilled if its root mean square (RMS) voltage and frequency coincide with the grid's RMS voltage and frequency during synchronization.

4. Result and Discussion

The Matlab inverter connected grid provides power to residential demand by connecting to the utility grid. It is composed of several components, including an ideal switch, an 80W photovoltaic (PV) module, a maximum power point (MPP) perturb and observe (PandO) tracker, a half bridge inverter, a step-up transformer, a coupling inductor, and an ideal transformer. The results are acquired through simulating the PV module under diverse conditions, encompassing significant uniform fluctuations in irradiance at a consistent temperature of 25°C, linear and abrupt rises in temperature at a consistent irradiance, alterations in both irradiance and temperature, and fluctuations in residential load. Displayed below are the waveforms generated through the simulation of the method using MATLAB in Figure 164.6.

Both the inverter voltage and current exhibit reduced harmonic content, and the highest overall harmonic for the inverter current is 3.66%. These harmonic distortion values met the high-power quality requirements of the IEEE and IEC internationally.

The PV panel's voltage waveform is shown in Figure 164.8. The Luo converter's input current is shown in Figure 164.9(a). Figure 164.9(c) shows the Luo converter's output current, while Figure 164.9(b) shows the enhanced output voltage of 600V in Figure 164.7.

5. Conclusions

The increasing environmental problems associated with pollution and global warming have led to a significant increase in the use of energy storage and renewable energy sources (RES) in modern power networks. With so many benefits and uses in both urban and rural areas, solar energy has become one of the main players in this space. Significantly, developments in solar photovoltaic (PV) technology have made it easier to integrate PV power systems with grid inverters, with an emphasis on increasing power output and efficiency. Using a Luo-convertor in conjunction with a modified Perturb and Observe (PandO) algorithm is a big step in the right direction for power extraction optimization from PV modules. This novel method overcomes the drawbacks of traditional PandO algorithms by utilizing load-based methodologies, allowing for a more precise assessment of power changes caused by load variations or weather. The results of using this updated algorithm with the Luo converter show excellent tracking of maximum power even in the face of abrupt changes in load or environmental conditions. As a result, this study highlights the possibility of combining cutting-edge control methods with renewable energy systems to increase their effectiveness and clear the path for a more sustainable and environmentally friendly energy future.

165 A prototype of an automatic baby cradle powered by solar energy

Arti Badhoutiya

Department of Electrical Engineering, GLA University, Mathura, India

Abstract: To improve newborn care, the solar-powered smart baby cradle combines cutting-edge technology and renewable energy sources. It uses solar panels to transform light from the sun into electrical energy that is then stored in rechargeable batteries. This energy is then used to power features like climate control, real-time health monitoring, and automated rocking. Through voice assistant integration, smartphone app management, and ongoing safety features like fall detection and battery backup, the cradle offers simplicity. Along with predictive maintenance alerts and sleep tracking, it has a lightweight, customizable design. By utilizing sustainable energy, this cradle not only guarantees the baby's comfort and safety but also encourages environmentally friendly lifestyle.

Keywords: Smart home system, sleep tracking, weight sensor, health monitoring, temperature control

1. Introduction

The creation of the Internet of Things is one of the most rapid and fascinating developments in information and communication technology today. Although networking technologies have grown over the past 20 years, their primary use has been to connect traditional end devices, such as desktop, laptop, and mainframe computers, as well as, more recently, tablets and smart phones. been used to connect traditional end gear, such as desktop, laptop, and mainframe computers, as well as, more recently, tablets and smartphones [1]. Taking care of infants has become a very difficult chore due to the rising demands of modern living and people's busy lifestyles. Infants require constant attention and supervision from their carer. But as technology has advanced, smart baby cribs have become more popular, lightening the load on parents and other carers.

Currently, a significant number of women are employed in industrialised nations, which has an impact on baby care in many households. Because of the high expense of living, both parents must work. They still have to take care of their infants, though, which adds to their workload and stresses them out—especially the mother. Babies cannot always be cared for by working parents. They either hire a babysitter to watch the children while they are at work or send the children to their parents. When their babies are in the care of others, some parents worry about their safety.

So, when they have free time, such at lunch or tea break, they return home to see how their babies are doing. To address these issues, it is suggested to implement a real-time infant monitoring system. Typically, newborns to four months old use the bassinet. Getting enough restful sleep is essential for maintaining good health. A baby grows more the more good sleep he or she receives. As a result, several kinds of beds created specifically for newborns have existed for ages [2]. By then, the design of this bed or cradle has advanced in accordance with requirements.

2. Technological Advancements in Making Baby Cradles Smarter

2.1. Safety features

a. Real-time Monitoring:
   - Video and Audio Monitoring: Integrated cameras and microphones to keep an eye on the baby remotely.
   - Health Monitoring Sensors: Track the baby's vital signs like heart rate, breathing, and temperature.
   - Fall Detection: Sensors to detect if the baby tries to climb out or if the cradle tips over.
b. Alerts and Notifications:
   - Sleep Pattern Alerts: Notifications for irregular sleep patterns.

- Health Alerts: Immediate alerts if any vital signs are abnormal.
- Movement Alerts: Notifications if the baby moves too much or tries to get out of the cradle.

2.2. Comfort features

a. Automated Rocking:
- Adjustable Rocking Speed and Patterns: Different settings to suit the baby's needs and preferences.
- Smart Rocking: Automatically adjust rocking based on the baby's crying or fussing patterns.
b. Climate Control:
- Temperature and Humidity Control: Maintain an optimal environment within the cradle.
- Air Purifiers: Ensure the air around the baby is clean and free from pollutants.

2.3. Convenience features:

a. Integration with Smart Home Systems:
- Voice Control: Compatible with voice assistants like Alexa, Google Home, etc.
- Mobile App Control: Control and monitor the cradle from a smartphone app.
b. Sleep Tracking and Analysis:
- Sleep Reports: Detailed reports on the baby's sleep patterns and quality.
- Recommendations: Provide insights and tips for improving the baby's sleep.
c. Entertainment and Soothing:
- Built-in Speakers: Play lullabies, white noise, or calming music.
- Night Light: Gentle lighting with adjustable brightness and color.

2.4. Power and efficiency

a. Enhanced Solar Efficiency:
- Efficient Solar Panels: High-efficiency solar panels to ensure reliable power supply.
- Battery Backup: Ensure the cradle operates during low sunlight conditions or at night.
b. Energy Management:
- Power Usage Monitoring: Track and optimize energy usage.
- Eco Mode: Minimize energy consumption when not in use.

2.5. Additional features

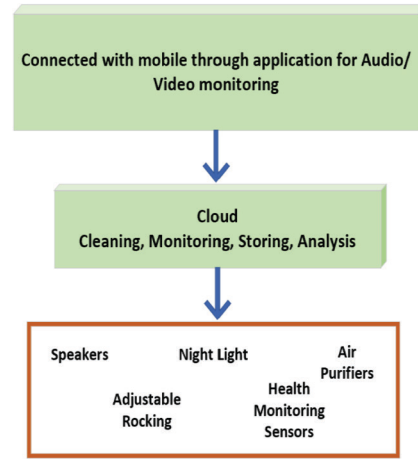
a. Customization Options:
- Customizable Appearance:
- Different designs, colors, and materials to suit personal preferences.


Figure 165.1. Smart cradle model prototype.

Source: Author.

- Modular Add-ons: Additional features or upgrades that can be added as needed.
b. Portability:
- Foldable Design: Easy to transport and store.
- Lightweight and Durable Materials: Ensure the cradle is easy to move without compromising on safety.

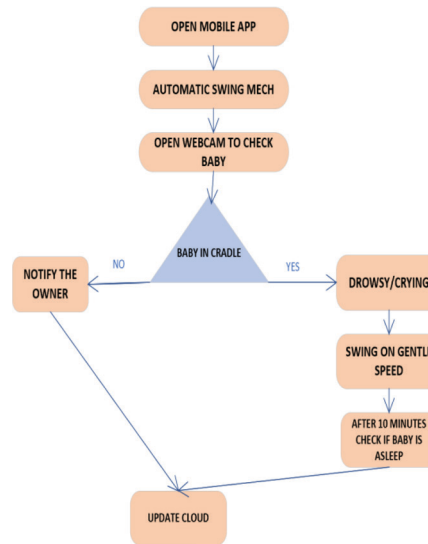
To improve new-born care, the solar-powered smart baby cradle combines cutting-edge technology and renewable energy sources [3]. It uses solar panels to transform light from the sun into electrical energy that is then stored in rechargeable batteries. This energy is then used to power features like climate control, real-time health monitoring, and automated rocking. Through voice assistant integration, smartphone


Figure 165.2. Flowchart of swing mechanism for cradle.

app management, and ongoing safety features like fall detection and battery backup, the cradle offers simplicity. Along with predictive maintenance alerts and sleep tracking, it has a lightweight, customisable design [4]. By utilising sustainable energy, this cradle not only guarantees the baby's comfort and safety but also encourages environmentally friendly living. A prototype of smart cradle is shown in Figure 165.1.

3. Mechanisms Included in the Smart Baby Cradle

A solar-powered smart baby cradle operates by harnessing solar energy to power various smart features that enhance the safety, comfort, and convenience of caring for a baby. The cradle is equipped with solar panels, typically mounted on the canopy or sides [5]. These panels capture sunlight and convert it into electrical energy.

The electrical energy is stored in rechargeable batteries to ensure a continuous power supply, even during low sunlight conditions or at night. The system includes a charge controller to manage the charging process and prevent overcharging or deep discharging of the batteries [6]. The stored energy is distributed to various components of the cradle through an efficient power management system. This system ensures optimal energy use and prioritizes essential features to maintain operation even when power is low. The cradle has a motorized rocking mechanism powered by the stored solar energy. Rocking speed and patterns can be adjusted manually or automatically based on the baby's needs. Smart sensors detect when the baby is fussing or crying and adjust the rocking motion accordingly. The flowchart of the mechanism of smart cradle is shown in Figure 165.2. The cradle includes temperature and humidity sensors to monitor the environment [7]. A built-in climate control system (fans, heaters, or humidifiers) maintains optimal conditions for the baby's comfort. Air purifiers can ensure clean air around the baby. Integrated cameras and microphones allow parents to monitor the baby in real-time through a connected smartphone app. Health monitoring sensors track vital signs like heart rate, breathing, and temperature [8]. The system sends alerts to the parents' smartphones if any abnormal conditions are detected, such as irregular sleep patterns or health issues. Built-in speakers play lullabies, white noise, or calming music to soothe the baby [9]. Gentle night lights with adjustable brightness and color provide a comforting environment for the baby. Parents can control and monitor the cradle through a dedicated smartphone app. The app allows for adjusting settings, receiving alerts, and viewing real-time video and audio feeds. The cradle can be integrated with voice assistants like Alexa or Google Home, enabling hands-free control through voice commands [10]. Sensors detect if the baby tries to climb out or if the cradle tips over. Immediate alerts are sent to the parents' smartphones, and the cradle can automatically stop rocking to prevent accidents. In case of prolonged low sunlight or power failure, the cradle's design includes a backup battery to ensure continuous operation. Essential features like health monitoring and alerts are prioritized during power-saving mode [11]. The cradle tracks the baby's sleep patterns and provides detailed reports through the smartphone app. AI and machine learning analyze the data to offer insights and recommendations for improving the baby's sleep quality. The system monitors the health of its components and alerts parents when maintenance or part replacement is needed. The cradle is designed to be lightweight and portable, with features like foldable components for easy transport and storage [12]. Customizable options for appearance and modular add-ons allow parents to tailor the cradle to their preferences and needs.

4. Conclusion

The sophisticated features of the solar-powered smart infant cradle are powered by electrical energy that is generated and stored by solar panels collecting sunshine. With the help of a smartphone app, users can manage the atmosphere for the ideal temperature and humidity, enjoy automated rocking with customisable speeds and patterns, and check their health in real time with audio, video, and alarms. In order to provide hands-free operation, it integrates with voice assistants and has safety features including fall detection and battery backup to guarantee continued functioning. In addition to tracking and analysing sleep habits, the cradle offers predictive maintenance alerts and is lightweight and easily portable thanks to its customisable design. This cradle promotes sustainable living while improving the comfort of the baby and the convenience of the parents through the use of cutting-edge technology and renewable energy.

166 Green sea ports—A futuristic idea

Arti Badhoutiya

Department of Electrical Engineering, GLA University, Mathura, India

Abstract: Seaports have a significant environmental impact since they are essential centers of international trade. Their activities have a major impact on noise pollution, water and air pollution, and greenhouse gas emissions. The potential of managing renewable energy resources as a tactical method to lessen these environmental effects and make seaports sustainable will be examined in this research study. Once considered a futuristic idea, green seaports are quickly becoming essential due to rising environmental concerns. The paper investigates the viability of green seaports as a response to the environmental issues facing the marine sector. It explores how to integrate carbon management plans, renewable energy sources, biodiversity preservation, and technology breakthroughs to achieve the goals of a green port. Green ports are evaluated in terms of their technical feasibility, economic viability, and environmental advantages. Although there are early investments and legal barriers to overcome, green seaports offer significant long-term benefits in the form of financial savings, decreased environmental impact, and improved port reputation, making them an appealing option for the future of maritime trade.

Keywords: Green ports, sustainability, renewable energy, carbon management, biodiversity, economic viability, technical feasibility

1. Introduction

The shipping industry is under pressure to reduce its environmental impact, leading to the development of green port initiatives. The integration of RETs in green ports is a key strategy for achieving sustainable practices and reducing the environmental footprint. The maritime sector, including ports, has traditionally been a significant contributor to greenhouse gas emissions and environmental degradation. The increasing pressure to reduce these impacts has spurred research into the potential of renewable energy as a viable alternative to fossil fuels [1]. This section will delve into existing research on renewable energy in this context, examining key findings, challenges, and opportunities. Figure 166.1. depicts different renewable options available for green ports.

a) Offshore Wind: A substantial body of research focuses on the potential of offshore wind energy to power maritime operations. Studies have explored the technical feasibility, economic viability, and environmental impacts of offshore wind farms in various coastal regions.

b) Wave and Tidal Energy: While still in its early stages compared to offshore wind, research on wave and tidal energy for maritime applications is growing. Studies have investigated the energy potential of different wave and tidal regimes, as well as the development of suitable energy conversion technologies.

c) Solar Energy: Solar power has been explored for applications in ports, including powering port facilities and charging electric vehicles. Research has focused on the integration of solar panels into port infrastructure and the economic benefits of solar energy adoption [2].

d) Biofuels: The use of biofuels in marine transportation is another area of research. Studies have examined the potential of different biofuel feedstocks, their environmental impacts, and the technical challenges of using biofuels in marine engines.

Research has highlighted the importance of energy efficiency measures in reducing port energy consumption. Studies have identified opportunities for energy savings in various port operations, such as cargo handling, ship-to-shore power, and port lighting. The development of energy management systems for ports has been a focus of research. These systems aim to optimize energy consumption, integrate renewable energy sources, and reduce operational costs. Research has explored the challenges and opportunities of integrating renewable energy into port power grids [3]. Studies have investigated the impact of variable renewable energy generation on grid stability and the role of energy storage systems in mitigating these challenges.
Figure 166.1. Different renewable options in green ports.

Source: Author.

2. Environmental Impact Assessments of Renewable Energy in the Maritime Sector

- Life Cycle Assessments: Life cycle assessments (LCAs) have been conducted to evaluate the environmental impacts of renewable energy projects in the maritime sector. These studies have compared the environmental performance of different renewable energy options with conventional fossil fuels.
- Ecological Impacts: Research has examined the potential ecological impacts of renewable energy installations, such as offshore wind farms and wave energy converters. Studies have focused on the effects on marine ecosystems, bird and bat populations, and underwater noise pollution.
- Socioeconomic Impacts: The socioeconomic impacts of renewable energy projects in coastal communities have been assessed. Studies have explored job creation, economic development, and public acceptance of renewable energy installations.

While the technical feasibility of various renewable energy technologies has been demonstrated, challenges related to energy conversion, grid integration, and energy storage still exist. The economic competitiveness of renewable energy in the maritime sector often depends on government support policies, such as feed-in tariffs or subsidies [4]. The environmental impacts of renewable energy projects can vary depending on the technology and location. Careful planning and mitigation measures are essential to minimize negative impacts. The development of clear and supportive policies and regulations is crucial for the successful deployment of renewable energy in the maritime sector.

3. Green Port Management

Green ports are essential in mitigating climate change and preserving marine ecosystems. This section will delve into specific strategies for carbon management and biodiversity protection within these critical infrastructure

hubs [5]. Carbon management in ports involves reducing greenhouse gas emissions, improving energy efficiency, and potentially capturing and storing carbon. The port operations can be optimized by implementing advanced technologies for cargo handling, vessel traffic management, and equipment utilization. Energy-efficient infrastructure can be achieved by constructing energy-efficient port facilities, including buildings, warehouses, and lighting systems [6]. Feasibility of capturing carbon emissions can be assessed from port-related activities and storing them underground. The energy supplied to the ship through smart grid is shown in Figure 166.2.

4. Environmental Concerns in Green Ports

Despite the name, green ports still face significant environmental challenges. While they strive to minimize their impact, there are inherent issues associated with port operations.

Air Pollution: Even with the adoption of cleaner technologies, port activities, including ship emissions, cargo handling, and vehicle traffic, contribute to air pollution.

a. Water Pollution: Ports can be sources of water pollution through oil spills, chemical runoff, and sediment discharge.
b. Noise Pollution: The constant activity in ports, including ship horns, machinery, and traffic, can lead to noise pollution affecting both port workers and nearby communities.
c. Habitat Destruction: Port expansion and construction can lead to the destruction of coastal ecosystems, affecting biodiversity.
d. Waste Management: Ports generate large amounts of waste, including hazardous materials, which requires proper management to prevent environmental contamination.
e. While these challenges are substantial, green port initiatives aim to mitigate these impacts through a variety of strategies, including cleaner technologies, waste management programs, and ecosystem restoration.
Figure 166.2. Energy supplied to the ship through urban power grid.

Source: Author.

5. Economic Viability of Green Ports

The transition to green operations requires significant upfront investments in renewable energy infrastructure, energy storage systems, and environmentally friendly equipment. While long-term energy savings can offset operational costs, there might be increased expenses in the initial stages. Adhering to environmental regulations can incur additional costs. Improved energy efficiency and reduced reliance on fossil fuels can lead to long-term cost savings [7]. Green ports can attract environmentally conscious businesses and customers, generating additional revenue. Many governments offer financial incentives and tax breaks for green initiatives, reducing the financial burden. A green reputation can enhance the port's image, attracting more business and investment. while the initial costs of green port development can be substantial, the long-term economic benefits and potential for revenue generation make it a viable investment [8]. Moreover, the increasing pressure to address climate change and environmental concerns is driving a global shift towards sustainability, making green ports a strategic business decision.

6. Future Research Directions of Green Ports

The technical feasibility of green ports hinges on several factors, including the availability and cost-effectiveness of renewable energy technologies, the capacity of energy storage systems, and the efficiency of grid integration. Challenges lie in the intermittency of renewable energy sources, requiring robust energy management systems [9]. Additionally, the integration of green infrastructure, such as green roofs and rainwater harvesting, within the port environment presents technical hurdles. Furthermore, the compatibility of green technologies with existing port operations and infrastructure must be carefully considered to ensure seamless implementation and avoid operational disruptions. These include developing advanced energy storage systems to fully harness intermittent renewable energy sources, exploring carbon capture and utilization technologies to create a circular carbon economy within ports, and conducting in-depth life cycle assessments to evaluate the true environmental impact of various green port initiatives. Additionally, research into the social and economic implications of green port development is crucial for ensuring equitable and sustainable transitions [10]. A deeper understanding of emerging technologies, such as artificial intelligence and blockchain, for optimizing port operations and supply chain sustainability is also essential.

7. Conclusion

It is anticipated that this research will offer important fresh perspectives on how renewable energy may help seaports lessen their environmental impact. Policymakers and port authorities can use the created framework as a reference for organising and carrying out sustainable port operations. Furthermore, this paper will add to the expanding corpus of information on renewable energy in the marine industry. Although there has been a lot of development in the field of renewable energy research for the maritime industry, more research is required to address the remaining issues and hasten the shift to a low-carbon maritime sector. Through the convergence of economic analysis, environmental impact assessments, and technology improvements, viable strategies for integrating renewable energy into port operations can be devised.

167 Space allocation monitoring based on sensors

Arti Badhoutiya

Department of Electrical Engineering, GLA University, Mathura, India

Abstract: The utilisation of sensors for space allocation monitoring is a novel method for optimising building utilisation. Organisations can obtain up-to-date information on environmental conditions, usage trends, and space occupancy by installing a variety of sensors throughout a building. Facility managers can use this data to make well-informed decisions about energy efficiency, resource optimisation, and space allocation. Building occupancy is essential for controlling buildings in a way that saves energy. A lot of work has gone into estimating and figuring out whether a facility is occupied. In order to make up for this, sensor fusion techniques are being employed in an effort to more precisely detect whether a space is inhabited by employing a variety of interior environment parameters. Considering that several sensors are commonly utilised to merge and estimate who is within a structure. This paper examines systems that use a variety of sensor configurations.

Keywords: PIR sensor, occupancy, HVAC systems, pyroelectric sensor

1. Introduction

Sensor-based space allocation monitoring revolutionizes building management by optimizing space utilization. By deploying various sensors (occupancy, environmental, desk booking), real-time data on space occupancy, usage patterns, and environmental conditions is collected. This data is analyzed to identify underutilized and overutilized spaces, calculate space utilization metrics, and optimize environmental factors. The insights gained enable informed decisions about space allocation, such as implementing hot desking or adjusting meeting room sizes. Benefits include improved space utilization, resource allocation, occupant experience, cost reduction, and data-driven decision making [1]. Challenges encompass data privacy, sensor accuracy, data analysis complexity, infrastructure costs, and change management. Future trends involve integrating with IoT, utilizing AI, and developing privacy-preserving technologies. This approach is applicable across various sectors, including offices, retail, education, and healthcare. For instance, in office buildings, it optimizes desk sharing, meeting room utilization, and HVAC systems. In retail spaces, it analyzes customer traffic patterns for improved store layout and staffing. Overall, sensor-based space allocation monitoring empowers organizations to create smarter, more responsive workspaces by leveraging data-driven insights.

Passive infrared, or PIR, has found extensive use because to its inexpensive cost and straightforward operation. However, in a previous study, the delay of passive infrared (PIR) resulted in inaccurate estimation, making it impossible to create the occupancy model [2]. Even the data collection methods will always differ if the modelling techniques are always the same. The PIR sensor is an electrical device that uses energy levels to detect the presence of other objects. Its detection accuracy ranges from eighty to ninety percent. The PIR sensor has rapidly overtook all other sensor types in popularity since they are inexpensive and simple to install. Its detection accuracy ranges from eighty to ninety percent. Because PIR sensors are inexpensive and simple to install, they have swiftly risen to the top of the sensor market. As a result, it is now widely used for occupant movement detection [3]. The PIR sensor's signal was passed via an amplifier and filter before being sent back to the gateway, greatly increasing the occupancy detection system's accuracy.

Things (items) can be linked to the internet and Figure 167.1. Sensors employed for vacancy detection communicate with one other in global online spaces by means of the Internet of Things (IoT) paradigm and its accompanying technologies. The Internet of objects enables users to communicate information with anything or anybody at any time or location since it links people and objects in ever-present settings.

Figure 167.1. Shows different sensors available for building occupancy detection.

Source: Author.

2. Motion Sensor Based Occupancy Detection

Motion sensor-based occupancy detection is a widely employed technology that leverages the detection of movement to infer human presence. This method relies on various sensor types, each with its own strengths and weaknesses. Passive Infrared (PIR) sensors are the most common. They detect changes in infrared radiation emitted by moving bodies. When a person enters the sensor's field of view, their body heat causes a variation in infrared levels, triggering the sensor [4]. Ultrasonic sensors operate by emitting high-frequency sound waves and detecting changes in their echo patterns caused by movement. Doppler radar sensors utilize electromagnetic waves to detect motion by measuring the Doppler shift of reflected signals. These sensors offer broader coverage and can penetrate obstacles compared to PIR and ultrasonic sensors.

Motion sensor-based occupancy detection is relatively straightforward and cost-effective. It provides a quick and reliable method for determining whether a space is occupied or vacant. These systems are widely used in various applications, including lighting control, security systems, and building automation. However, they have limitations. PIR sensors can be affected by air currents, pets, and changes in ambient temperature, leading to false positives or negatives. Ultrasonic sensors might be susceptible to noise interference, while Doppler radar sensors can be expensive and consume more power [5]. To enhance accuracy and reliability, motion sensors can be combined with other technologies, such as CO_2 sensors or climate sensors. This approach provides complementary data and helps compensate for the individual limitations of each sensor type. Additionally, advanced signal processing algorithms can be employed to filter out noise and improve detection performance. While motion sensor-based occupancy detection remains a popular choice, the specific sensor technology and implementation details should be carefully considered based on the application and environmental conditions. By addressing the potential challenges and combining motion sensors with other sensing modalities, it's possible to create robust and efficient occupancy detection systems.

3. IR Based Occupancy Detection

R-based occupancy detection utilizes infrared (IR) radiation, invisible to the human eye, to determine if a space is occupied. Humans and animals emit IR due to body heat. Passive Infrared (PIR) sensors are commonly used. These detect changes in IR levels within their field of view. When a person enters, the sensor detects increased IR, signaling occupancy. A microcontroller processes this data, activating devices like lights or HVAC systems accordingly [6].

This technology offers low cost, low power consumption, and ease of installation. It's widely used for energy efficiency, security, and building automation. However, it's sensitive to air currents and may struggle with stationary objects. Combining PIR sensors with other technologies can improve accuracy. This device detects changes in infrared radiation levels within its field of view. When a person or animal enters the sensor's range, their body heat increases the IR radiation, triggering the sensor. This change is then processed by a microcontroller, which determines if the detected change indicates occupancy. A PIR sensor typically consists of a pyroelectric sensor and a Fresnel lens. The pyroelectric sensor converts changes in temperature into electrical signals. The Fresnel lens focuses the infrared radiation onto the sensor, increasing its sensitivity. Once the microcontroller confirms occupancy, it can activate various devices, such as lights, HVAC systems, or security alarms. This automation contributes to energy efficiency, improved security, and enhanced comfort.

4. Advantages and Limitations

IR-based occupancy detection offers several advantages. PIR sensors are relatively inexpensive. They require minimal power to operate. These sensors are simple to set up. They do not capture visual data. PIR sensors have a proven track record of accuracy in detecting human presence. However, there are also limitations. False triggers can occur due to air movement. PIR sensors primarily detect motion. Pets can trigger the sensors, leading to false positives. The detection range of PIR sensors is relatively short [7]. Accurately

detecting multiple people in a space can be challenging. To overcome these limitations and improve the overall performance of IR-based occupancy detection, several strategies can be employed. Combining with other technologies: Integrating PIR sensors with ultrasonic or radar sensors can enhance accuracy and overcome the limitations of each individual technology. Sophisticated algorithms can be used to analyze sensor data more effectively, reducing false positives and improving detection accuracy. Careful consideration of sensor placement can optimize performance by minimizing interference from air currents and other factors. Regular calibration of PIR sensors can help maintain accuracy over time. Creating occupancy profiles based on historical data can improve system responsiveness and energy efficiency.

5. Climate Sensors Based Occupancy Detection

Climate sensors, traditionally employed for environmental monitoring, have shown potential for occupancy detection. The underlying principle is that human presence significantly influences indoor climate parameters. By meticulously tracking these changes, it's possible to infer occupancy patterns. Temperature, humidity, and air pressure are the primary climate factors considered. Human bodies emit heat, increasing ambient temperature. Respiration adds moisture to the air, elevating humidity levels. While the impact on air pressure is less pronounced, it can still contribute to overall climate variations. By establishing baseline climate conditions for an unoccupied space and continuously monitoring for deviations, occupancy can be inferred. A sudden and sustained increase in temperature and humidity, for instance, typically indicates human presence. Conversely, a return to baseline conditions suggests an empty space.

This method offers certain advantages. It provides continuous occupancy data, unlike motion-based sensors which only detect movement. Climate sensors also contribute to overall indoor comfort by regulating temperature and humidity based on occupancy. Moreover, they can be used to monitor building energy efficiency by correlating climate conditions with occupancy patterns. However, challenges exist [8]. External factors such as weather conditions, building insulation, and ventilation systems can influence indoor climate, potentially affecting detection accuracy. Additionally, multiple occupants or varying activity levels can complicate the interpretation of climate data [9]. To address these issues, advanced algorithms and calibration procedures are essential.

In practical applications, climate sensor-based occupancy detection finds utility in various settings.

Smart buildings can optimize energy consumption by adjusting heating, cooling, and ventilation based on occupancy. Various steps involved in building occupancy detection is shown in Figure 167.2. Commercial spaces can use this technology to analyze customer behavior and optimize store layout. Healthcare facilities can monitor patient occupancy in rooms, aiding in staff allocation and resource management. While climate sensors offer a promising approach to occupancy detection, it's crucial to consider the specific environment and application. Combining climate sensors with other sensing technologies, such as CO_2 or motion sensors, can enhance accuracy and reliability. By carefully addressing the limitations and leveraging the strengths of climate sensor data, it's possible to develop robust occupancy detection systems.

6. CO_2 Sensors Based Occupancy Detection

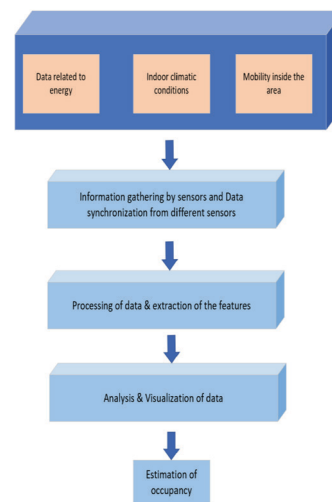
CO_2 sensors, traditionally employed for indoor air quality monitoring, have emerged as a promising technology for occupancy detection. The principle is straightforward: humans exhale CO_2 as part of respiration. Consequently, an increase in CO_2 levels within a space often correlates with an increase in occupancy. CO_2 sensors measure the concentration of carbon dioxide in the air. By establishing a baseline CO_2 level for an unoccupied space and continuously monitoring for changes, it's possible to infer occupancy patterns. A significant and sustained rise in CO_2 levels typically indicates human presence. Conversely, a gradual decline suggests an empty space. This method offers several advantages over traditional occupancy detection methods. Firstly, it provides a continuous


Figure 167.2. Steps to detect vacancy.

Source: Author.

measure of occupancy rather than relying on motion detection. This allows for more accurate occupancy estimation, especially in static environments like classrooms or offices. Secondly, CO_2 sensors contribute to improved indoor air quality by monitoring ventilation needs. By correlating CO_2 levels with occupancy, ventilation systems can be adjusted accordingly, enhancing occupant comfort and well-being. However, there are challenges associated with CO_2-based occupancy detection. External factors such as outdoor CO_2 levels, ventilation rates, and the number of occupants can influence the accuracy of the system [10]. Additionally, prolonged occupancy without adequate ventilation can lead to CO_2 buildup, potentially saturating the sensor and affecting its reliability. To address these limitations, advanced algorithms and calibration techniques are often employed. In practical applications, CO_2-based occupancy detection finds utility in various settings. Smart buildings can optimize energy consumption by adjusting lighting, heating, and cooling based on real-time occupancy data. In healthcare facilities, it can help monitor patient occupancy in rooms, aiding in staff allocation and resource management. Educational institutions can utilize CO_2 sensors to assess classroom utilization and inform ventilation strategies. While CO_2 sensors offer a compelling alternative to traditional occupancy detection methods, it's essential to consider the specific environment and application when implementing this technology. By carefully addressing the limitations and combining CO_2 sensors with other sensing modalities, it's possible to achieve accurate and reliable occupancy detection systems.

7. Conclusion

Significant options exist to enhance building efficiency, tenant happiness, and operational costs through sensor-based space allocation monitoring. Employing data-driven insights, companies may design more intelligent and adaptable work environments. Occupancy detection systems in buildings provide controlled lighting and ventilation, which saves energy and preserves comfort. However, because to their limitations, PIR and environmental sensors are always prone to errors in person recognition and data collection. Improving occupancy predictions' accuracy could help close the gap between what happened and what was expected. This research looks at systems that employ many sensor combinations.

168 Real-time sag detection and line stand fall protection for overhead transmission lines

Yogendra Kumar

Department of Electrical Engineering, GLA University, Mathura, India

Abstract: The integrity of the electrical grid is seriously threatened by unanticipated line sag in overhead transmission lines, which can result in large blackouts. A new Internet of Things (IoT)-based system for real-time sag detection and line stand fall prevention is proposed in this research. To precisely detect sag at different spans over a single circuit, the system makes use of a sag-sensing module that is outfitted with a tri-axial accelerometer. The accuracy of the conversion of the recorded accelerometer parameters into line sag values is 2.09% on average, as confirmed by rigorous field testing on two 161-kV lines. The system also includes an MPU6050 sensor for line stand position and connection detection, which allows for real-time stand integrity monitoring and fall detection. LoRa wireless technology transmits data to a central station, enabling quick intervention and response. In addition to improving power grid resilience and lowering the danger of blackouts, this complex system provides a strong and dependable means of guaranteeing the safety and integrity of overhead transmission lines.

Keywords: Sag detection, line stand fall protection, IoT, accelerometer, real-time monitoring, power grid resilience

1. Introduction

Internet of Things -based sag monitoring system that uses an embedded three-axis accelerometer and IoT algorithms to deliver real-time sag information of a transmission line. On a high voltage transmission line and its surroundings, this dependable monitoring device detects sag-related information directly in real time. The electrical grid, the lifeblood of contemporary society, is always under danger from unexpected line sag in overhead transmission cables. In order to minimize the possibility of catastrophic outages, this task demands creative solutions that can not only identify sags in real-time but also avoid line stand failures. To improve the security and resilience of the power grid, this study suggests a unique Internet of Things -based solution that guards against line sag and stand failures. Our technology makes use of the Internet of Things' disruptive potential by placing modules in important locations that are outfitted with cutting-edge sensors to continuously monitor vital transmission line characteristics. A tri-axial accelerometer is housed in a sag-sensing module, which is the central component of the system. The system has an MPU6050 sensor that

is responsible for line stand position and connection integrity monitoring in addition to sag detection. This crucial sensor makes it possible to continuously monitor the health of the stand in real time and quickly identify any possible faults before they become catastrophic occurrences. With its combination of precise sag detection, real-time stand monitoring, and quick communication capabilities, the suggested Internet of Things -based system provides a comprehensive solution.

2. Literature Survey

H. Al-Asaad, H. Noura, A. Mohamed, A. Yousef, and A. Ahmad [1] presents a real-time fault detection and localization system for distribution power grids using IoT and machine learning. It proposes an integrated framework that combines IoT devices, data analytics, and machine learning algorithms. The system utilizes sensors and smart meters distributed across the power grid to collect real-time data. Machine learning algorithms are trained to detect and classify different types of faults based on historical data. The paper also addresses fault localization, using collected sensor

data and network topology information to estimate fault location. The proposed system enhances power grid reliability by enabling prompt identification and localization of faults for timely maintenance and restoration activities.

S. Sathiyarajan and N. Anantharaman [2] presents an IoT-based real-time monitoring and alert system for detecting line sags in overhead power lines. The system utilizes IoT sensors installed along the power lines to measure sag parameters. It sends real-time alerts when abnormal sag levels are detected. The paper describes the system architecture, sensor deployment, and data processing techniques used for sag detection. The proposed system enhances the monitoring and detection of line sags, enabling timely actions to maintain power grid stability and reliability.

T. Kundu, M. B. Nayak, and P. Ray [3] proposes an intelligent line sag monitoring and alarm system for overhead power distribution networks using IoT. The system uses sensors and wireless communication to collect and transmit sag data in real-time. It employs machine learning algorithms for data analysis and fault detection. The paper discusses the system architecture, sensor deployment, and machine learning algorithms used able to be widely implemented on large-scale power grid systems. for sag detection. The proposed system enables timely detection of line sags, improving power grid reliability and minimizing system downtime.

R. Chayapathi and B. Chiranjeevi [4] focuses on the detection of line sags and swells in power transmission and distribution systems using IoT. It proposes an IoT-based monitoring system that utilizes voltage and current sensors deployed across the grid. The system detects and classifies sag and swell events in real-time. The paper discusses the system architecture, sensor deployment strategy, and experimental results. The proposed system enhances the monitoring capabilities of power grids, enabling timely detection and classification of line sags and swells for improved system stability and reliability.

H. A. Khalaf and M. J. Abdulraheem [5] presents an IoT-based sag detection and localization system for overhead power distribution networks. The system utilizes IoT devices, such as sensors and communication modules, to collect real-time data on sag events. Machine learning algorithms are appl ied to analyze the collected data and detect sags. The paper discusses the system architecture, sensor deployment, and experimental results. The proposed system offers an efficient and reliable solution for detecting and localizing sags in overhead power distribution networks, enhancing grid stability and minimizing downtime.

A. S. Rathore, R. A. Jotwani, and V. Jain [6] focuses on smart grid line sag detection using IoT. It presents a system that utilizes IoT devices and sensors to monitor power grid lines for sag events. The collected data is analyzed using machine learning algorithms to detect and classify sags. The paper discusses the system architecture, sensor deployment, and experimental results. The proposed system offers an effective approach for real-time sag detection in smart grids, contributing to enhanced grid monitoring and maintenance.

M. A. Aljarrah, A. S. O. Youssef, and R. S. Obaidat [7] presents a novel IoT-based system for sag detection in power distribution grids. The system utilizes IoT devices and sensors to collect real-time data on sag events in the grid. Machine learning algorithms are employed to analyze the collected data and detect sags accurately. The paper discusses the system architecture, sensor deployment strategy, and experimental results. The proposed system offers a reliable and efficient solution for sag detection in power distribution grids, enabling prompt actions to maintain grid stability and reliability.

V. Thanh Nguyen, N. T. V. Thang, T. Q. Thanh, and P. H. Duc [8] introduces a line sag detection and classification system in power grids using IoT and machine learning. The system employs IoT devices and sensors for real-time data collection on line sags. Machine learning algorithms are utilized to analyze the collected data and classify different types of line sags accurately. The paper discusses the system architecture, sensor deployment, and experimental results. The proposed system offers an effective approach for line sag detection and classification, contributing to improved monitoring and maintenance of power grids.

FF. Albu, F. Keyrouz, and A. B. Nassereddine [9] proposes a smart grid monitoring system that utilizes IoT technologies for line sag detection and classification. The system employs IoT devices and sensors to collect real-time data on line sags in the grid. The collected data is analyzed using machine learning algorithms to detect and classify different types of line sags. The paper discusses the system architecture, sensor deployment, and experimental results. The proposed system offers an efficient approach for line sag monitoring in smart grids, contributing to enhanced grid stability and reliability.

N. Garg, R. C. Jha, and S. Pradhan [10] proposes a method for detecting and localizing line sag in power distribution networks using Internet of Things (IoT) technology. The authors address the need for real-time monitoring of power lines to prevent power outages and ensure reliable electricity supply. Their approach involves the deployment of IoT devices equipped with sensors along the power lines to collect data on line sag. The collected data is then analyzed using signal processing techniques to detect and locate line sag events. The proposed method offers the potential to enhance the efficiency and reliability of power distribution networks by enabling proactive maintenance and timely fault detection. The effectiveness of the approach is evaluated through simulation and experimental results, demonstrating its feasibility and accuracy.

REQUIRED EQUIPMENT
    Hardware Requirements:
- Arduino nano
- LORA 2
- Relay -1
- Accelerometer-1
- Esp 8266
- Current sensor -1
- Power unit
- Voltage sensor
- LCD
    Software Requirements:
- Embedded c
- c++

2.1. Arduino nano

The Mini-B USB port, the 6-20V unregulated external power source (pin 30), or the 5V regulated external power supply (pin 27) may all be used to power the Arduino Nano in Figure 168.1. The greatest voltage source is automatically chosen as the power supply in Figure 168.2.

2.2. Voltage sensor

DC voltage is measured using a voltage transformer called the ZMPT101B. With this module, AC voltages up to 250 volts may be measured. This sensor produces analog data in Figure 168.3. The output voltage will alter in tandem with changes made to the input voltage in Figure 168.4.

2.3. Relay switch

A relay is an electromagnetic device that is used to join two circuits magnetically and electrically separate them in Figure 168.5. These are really helpful gadgets that

provide total separation between two circuits while allowing one to switch another. They are frequently utilized as an interface between low-voltage electronic circuits and high-voltage electrical circuits in Figure 168.6.

2.4. ESP8266

There are 17 GPIO pins on the ESP8266 12-E microcontroller. It is not advisable to utilize some GPIOs, and others are only available on certain ESP8266 development boards, while others are designed for certain purposes. You'll save hours of aggravation by utilizing the right pins for your projects after reading this article, which will teach you how to utilize the ESP8266 GPIOs correctly in Figure 168.7.

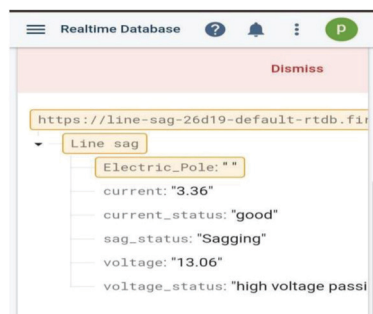
Lora
A secure, long-range, low-power wireless technology for M2M and Internet of Things applications is called LoRa. The low power features of FSK modulation, which may be used to long-distance communications, are shared by chirp spread spectrum modulation, the foundation of LoRa. LoRa allows for the wireless connection of many objects, including humans, animals, machines, gateways, and sensors, to cloud computing in Figure 168.8.


Figure 168.9. Real time database 2.

Source: Author.

2.5. Accelerometer

An electromechanical tool used to measure acceleration force is called an accelerometer in Figure 168.9. It solely displays acceleration as a result of gravity, or the g force. Acceleration is measured in g units.

LCD 16x2
An electrical display module with many uses is the LCD (Liquid Crystal Display) screen in Figure 168.10. A 16x2 LCD display is a relatively simple module that is frequently seen in many different kinds of circuits and devices. Compared to other multi-segment LEDs particularly those with seven segments, these modules are preferable. The reasons are as follows: LCDs can display unusual and even bespoke characters (unlike in seven segments); they are inexpensive; they are easily programmed; they can display animations; and so on.

2.6. Fire base

Firebase is a platform for creating mobile and web apps that offers developers a wide range of resources to help them create apps that are high-quality, increase their user base, and generate more revenue.

3. Proposed System Architecture

The suggested system is an Internet of Things (IoT) based transmission line stand fall and line detection

5. Conclusion

An Internet of Things-based SAG monitoring system for overhead transmission lines is a creative way to raise the dependability and effectiveness of power transmission networks. This system uses data analytics techniques and cutting-edge sensor technology to track the SAG of real-time monitoring of transmission lines to facilitate early problem diagnosis and preventative maintenance.

Insights regarding the operating behavior of transmission lines may be obtained from the system, which can be applied to enhance equipment longevity and performance. Additionally, the system's remote monitoring features can lessen the need for in-person inspections, increasing safety and cutting down on operating expenses.

But putting such a system into practice calls for careful planning and consideration of many different aspects, including sensor location, data processing, and communication infrastructure. Additionally, the system needs to be built to withstand challenging environmental circumstances so that precise and continuous monitoring is possible.

All things considered, an Internet of Things (IoT)-based SAG monitoring system for overhead transmission lines has the potential to completely change how power transmission networks are run while enhancing the system's dependability, effectiveness, and safety. Such creative ideas will be crucial to maintaining the

power grid's smooth and sustainable operation as the demand for electricity rises.

169 Enhancing load frequency control in interconnected power systems using PSO-tuned PI controller

Yogendra Kumar

Department of Electrical Engineering, GLA University, Mathura, India

Abstract: This study aims to improve the load frequency control (LFC) of a two-area linked power system by implementing a Proportional-Integral (PI) controller that has been optimized using Particle Swarm Optimization (PSO). The main goal of the investigation is to assess the performance of the system in relation to dynamic variables, such as settling time, overshoot, and undershoot. The results indicate that the proposed PI tuning method outperforms conventional PI controllers in terms of system performance metrics. Given the positive outcomes observed, it is feasible to apply this approach in more intricate situations, such as multi-area power systems with additional constraints, where sophisticated controller systems could enhance efficiency to a greater extent. This research demonstrates the indispensability of PSO-based tuning techniques in enhancing the efficiency and reliability of networked power systems. The simulation results exhibit superior performance compared to the PI controllers, as evidenced by performance indicators. The simulation is executed using MATLAB-Simulink.

Keywords: Dynamic parameters, PSO, load frequency control, multi-area power system, controller

1. Introduction

Maintaining numerous sets of balances correctly is the key to a power system's successful operation. Between load-generation and scheduled, real tie line flows, there are two of these balances [1, 2]. Major contributors to maintaining a steady frequency are these two balances. The main factor for both the system's smooth functioning and the quality of the electricity sent to the user is determined to be constant frequency. By altering generation while keeping load demand in mind, both of these balances are kept in check. Precise human management of these balances would be impossible due to the continually fluctuating load during different hours of the day, which causes system conditions to change [3].

The vertically integrated utilities (VIUs) that supplied power at regulated rates have been replaced in the electric power business by a reorganized system that includes competitive enterprises for distribution, transmission, and generating. LFC takes on a crucial role in the new power system architecture, facilitating power exchanges and improving the environment for trading in energy. Maintaining frequency and net interchanges at the targeted levels for every control area is one of the common LFC goals. Thus, a great deal of

study has been done to enhance the dynamical transient responsiveness of the system under competitive settings as well as to change the traditional LFC [4-9].

A thorough analysis of generation control in deregulated electricity networks may be found in [10]. There is also discussion on the idea of an independent system operator (ISO) acting as an impartial coordinator to strike a balance between reliability and economics [11]. The evaluation of Automatic Generation control (AGC) in a deregulated setting is demonstrated in [12], which also offers a thorough analysis of the matter and describes how an AGC system may be modelled following deregulation.

2. PI Controller

The proportional integral (PI) controller is preferred because of its strong capacity to resolve a wide range of real-world control issues and its straightforward construction. By enhancing the transient response, the PI controller lowers error and gradually settles the output to the final required value, ensuring stability. Equation 1 displays the PI controller's output equation.

$$y(t) = K_p e(t) + K_i \int e(\tau) d\tau$$
Figure 169.1. Block diagram of PI controller.

Source: Author.

Figure 169.1 displays the PI controller's block diagram. The error signal is represented by u(t), while the controller's output is y(t). The controller's proportional and integral gains are denoted by Kp and Ki. Conventional PI controllers have disadvantages, such as poor reaction times and low handling efficiency in non-linearity systems. Several optimization techniques, such the Ziegler-Nicolaus method and the genetic algorithm, are used to fine-tune these gains values.

3. Two Area Deregulated Power System For LFC

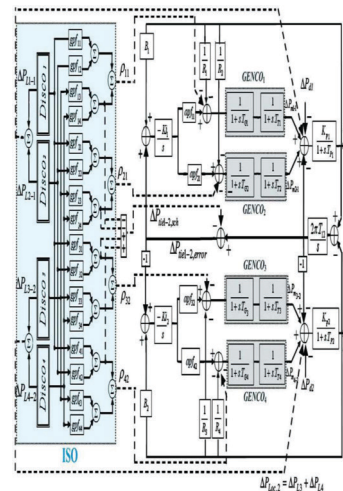
The disaggregated power grid will comprise four entities: GENCO, DISCO, TRANSCO, and ISO, which are the independent system operators. The initial objectives of the AGC, which aimed to reinstate the desired levels of frequency and net interchanges in each control region, have not been altered. Each of the two sites being investigated has two Generation Companies (GENCOs) and two Distribution Companies (DISCOs. Figure 169.2 displays the diagram of the deregulated power system with two areas. ISO oversees the power contracts between any GENCO and any DISCO that involve individual transactions. In the following section, we will explore the method of simplifying the display of contracts by utilizing the "DISCO participation matrix" (DPM).

The number of rows in a DPM matrix is directly proportional to the number of GENCOs in the system, while the number of columns is directly proportional

to the number of DISCOs. A DISCO (column) may have allocated a fraction of the overall burden to a GENCO (row) in this manner. Equation (2) represents the calculation of the DPM for the two area power system. The "contract participation factor" (gpfij) represents the ratio of the total load power of GENCO i that DISCO j has contracted. The percentage can be observed in the ijth entry.

4. Particle Swarm Optimization

The population-based optimization technique known as PSO was initially put out by Eberhart and Colleagues [14, 15]. One of PSO's appealing aspects is how simple it is to apply. It may be applied to a broad range of optimization issues. Similar to evolutionary algorithms, the PSO approach uses a population of particles, or people, to carry out searches. Every particle is a potential fix for the current issue. Particles in a PSO system move about in a multidimensional search space to adjust their locations until the computing capacity is reached. With just a few lines of coding, this innovative method may be quickly and easily implemented, offering several benefits. Furthermore, it has very few requirements. Furthermore, there are several advantages of this method over genetic and evolutionary algorithms. PSO has memory, first of all. To put it another way, each particle retains its global best answer. PSO has the additional benefit of maintaining its original population, which eliminates the requirement for the time-and memory-consuming operation of adding operators to the population. Furthermore, unlike genetic algorithms, which are predicated on the survival of the fittest, PSO is built on positive particle cooperation.

Figure 169.2. Two area power system.


Source: Author.

Figure 169.3. Model of the transfer function for two area power systems.

Source: Author.

Transfer function model of the two area deregulated power system is shown in Figure 169.3.

5. Simulation Results

In the event where all GENCOs in a given region engage in AGC equally, the ACE participation factors would be apf1 = 0.5, apf2 = 1-apf1 = 0.5, apf3 = 0.5, and apf4 = 1-apf3 = 0.5. Assume that only region I experiences the load adjustment. Therefore, only DISCO1 and DISCO2 are requesting the load. For each of them, let the load perturbation's value equal 0.1 pu MW.

Figures 169.4(a), 169.4(b), depict the tie line power flow for Case 1 with the PI controller, whose settling time, overshoot, and undershoot are displayed, as well as the dynamic response of regions 1 and 2. In the identical instance with a PSO-tuned PI controller, Figures 169.5(a), 169.5(b), depict the tie line power flow as well as the dynamic response of regions 1 and 2. The comparison with the PI controller reveals a decrease in the settling time, overshoot, and undershoot.

For both the PI and PSO-PI controllers, the settling time of the frequency shift in region 1 is 9.8 s and 8.9 s, respectively. The PSO-PI controller's settling time for the frequency shift in region 2 is 12 s, whereas the PI controller's is 27.4 s. When compared to a PI controller, the PSO-PI controller exhibits lower settling times, as well as lower overshoot and undershoot.

6. Conclusions

This paper presents a Proportional Integral (PI) controller that has been optimized using Particle Swarm Optimization (PSO) for the purpose of controlling load frequency in a deregulated electrical system. The continuous deregulation of the power sector and the rise of competing companies have increased the complexity of LFC issues, requiring additional research and understanding. The proposed PSO controller is designed to guarantee reliability and robustness in various operating conditions. Its main objective is to stabilize frequency oscillations in a two-area deregulated power system. The effectiveness of the proposed PSO adjusted PI controller is demonstrated through extensive MATLAB-Simulink simulations. It outperforms conventional PI controllers in various performance metrics over a wide range. This study enhances the dependability and effectiveness of the contemporary power grid by uncovering the capacity for advanced optimization techniques to enhance LFC control strategies in deregulated power systems.

170 Strategies and policies for sustainable natural energy resource management

Ankita Nihlani[1,a] and Naveen Singh Rana[2]

[1]Assistant Professor, Department of Management, Kalinga University, Raipur, India
[2]Department of Management, Kalinga University, Raipur, India

Abstract: A particular assessment strategy for strengthening how these interventions contribute to efficient resource use involves introducing a modern Natural Energy resource and Environmental Politics framework to priorities design improvements and adaptation and growth. Assessment is essential to identify change, promote a sufficiently flexible adaptive approach to address the threat of instability and promote person, group, institutional and political formation. Based on changing approaches to Natural Energy resource management, a set of principles has been developed for assessment in NRM are based on the following: addresses system-specific evaluation, objective connects with impact, assesses the underlying principles and expectations underpinning key strategy or system objectives; is focused on realistic implementation in the Natural Energy resource, political/institutional, environmental, socio-cultural and technical contexts, develop practical and appropriate evaluation criteria for tracking and assessing the change, require both quantitative and qualitative approaches in analytical humanism to ensure a rigorous and comprehensive assessment and incorporates various (i.e., social, economic, environmental, political, and technological) seasons change. The proposed paper establishes a Heuristic Sustainability Natural Energy resource Management approaches to integrate these concepts and sometimes recognizes NRM policy's multiple levels and networking features. The simulation results show the Heuristic Sustainability Natural Energy resource Management approach achieves 95% community-based analysis, 98% performance analysis, a 96% cost, a 13% resiliency, and a 97% Efficiency in representing the Natural Energy resource management.

Keywords: Natural energy resources, environmental policy, policies, heuristic sustainability, natural energy resource management (HSNRM)

1. Introduction

Sustainable use of Natural Energy resources means that Natural Energy resources are carefully controlled for the good of the entire human race. Trees are one of the most valuable Natural Energy resources for renewable energy production. In several regions of the planet, the depletion and loss of Natural Energy resources exacerbate scarcity's general issue. To improve the life span of Natural Energy resources, especially not renewable resources, and control environmental pollution, Natural Energy resources management's sustainability is essential [10]. The opportunities for the current generation are provided by sustainable Natural Energy resource management [11]. Sustainable Natural Energy resource management is essential because it helps leverage resources in future generations' wisdom without overuse and without sacrificing [13]. Reusing and recycling are better because it needs both resources and money

for the recycling of products. The main advantage of managing sustainability in Natural Energy resources is to discover the utilization of proper resources [27]. Natural Energy resource management aims to reverse the degradation trend in resources, preserve the ecological balance and sustain economic growth [17]. The management of the environment is similar to Natural Energy resources' power, and it is getting processed through specific policies and procedures regarding sustainability [19].

The main contribution of the revise is:

- Establishing environmental policies is essential in Natural Energy resource Management.
- They are analyzing different strategies based on the resource management processes.
- The changes regarding social, economic and environmental are going to be analyzed.
- Performing evaluation based on policy statements for tracking the changes

The rest of the paper will be arranged as follows: In section 1, the importance of NRM and its benefits have been discussed, followed by a detailed Literature Review in Section 2. In section 3, the Heuristic Sustainability Natural Energy resource Management (HSNRM) strategies, environmental policies will be concerned. The paper ends in Section 4 and 5 with experimental results, limitations, and future studies recommendation.

2. Literature Review

The CBNRM policies have a negative and positive influence on resilience, and domestic choices could address significant threats. The socio-ecological systems with a longer CBNRM tradition and more local buy-ins of common goals appear to be more resilient to environmental problems. Malin Song et al. [23] has introduced Sustainable Natural Energy resource management based on extensive data, Large-scale data on environmental emissions and prevention, Challenge in the world of green innovation, and Large Data green development modelling and mining. The results and suggestions are optimistic and encouraging. The paper focuses on many other topics that need to be dealt with, structures which can be developed and encouraged, and changes to competitive, sustainable and low-pollution. Based on the results above, lower-middle-income countries have to design a robust and efficient environmental policy. As a result, the policy suggestion should be made for increasing environmental resource management quality levels. Zhao, J., Liu, H., and Sun, W, et al. [25], proposed some Strategies and their Competition based on the Natural Energy resource perspective. Relevant organizational tools and skills of the firm are a big part of success. Sustainable Natural Energy resource management is implemented by applying environmental policies and strategies based on the above research.

3. Heuristic Sustainability Natural Energy resource Management and its Processes

Social welfare, sustainable economic development and social protection are the main pillars of development initiatives in most countries. With a specific objective as emerging markets, improving livelihoods and sustainable development can lead to a lack of access to Natural Energy resources, value-added products and services. Natural Energy resources, particularly soils, water, forests, plants and animals, greenery, renewable energy, and climate change, are essential. Excluding the Natural Energy resources can be handled best to enhance subsistence, minimize poverty and raise economic growth.

The term ecosystem typically refers to a Natural Energy resource base that provides sinks with sources and functions. The article focuses on sustainability and livelihood principles that reflect NRM objectives, scope and priorities to achieve development goals.

3.1. Case 1 analyzing natural energy resources eradication with examples

Management of nature is a scientific and technological term that forms a basis for the sustainable management and Natural Energy resources protection (e.g. land, water, soil, plants and animals). The emphasis is on the effects of power on present and future generations' quality of life. It is understood that Natural Energy resources contribute in a wide variety of ways to the development of the economy, such as the economic sector and the sources of growth; livelihood, jobs and environmental services.

The loss of biodiversity, for example, can affect ecosystems' functioning and resilience. Loss of biodiversity will reduce plant and soil organisms' diversity and decrease structural vegetation diversity, which will, in turn, cause nutrient loss and affect soil structure. It can contribute to lower nutrient cycling, soil depletion and soil erosion. The principal factor in reducing production and food insecurities are depletion and soil erosion. Soil erosion decreases carbon sequestration above and below the soil and raises CO_2 emissions, exacerbating climate change. Changes in the environment will result in higher costs.

3.2. Solution 1 ways to manage the spoiling of natural energy resources

Reducing Natural Energy resources is essential to sustaining the world's environment and alleviating climate change problems. Fortunately, a little training on the use of Natural Energy resources will lead to reducing people's usage. Reducing the use of several Natural Energy resources—trees, fuel and water—can significantly affect earth's overall sustainability. Reducing forest use will help offset climate change and habitat degradation. Climate change is a big concern. The forests play a crucial role in turning carbon dioxide into oxygen and preserving carbon in their wood, thus reducing atmospheric CO_2 content. Forests, however, have many other purposes, including flood control and topsoil and water conservation. Due to the significance of both of these activities, forest management is essential. Reduces the use of wood and turns forests into farmers, the world should aim to reduce paper and wood and eat Less Rind.

Figure 170.1 shows the elements causes natural degradation and how to avoid such natural exploitation.
Figure 170.1. Managing natural energy resources.

Source: Author.

The first analysis shows the water management resources with the hydrological cycle implementation; it created a new land cover map. The HRB is given cover charts. The classifying method, however, is not hydrological suitable—modelling and management of water supplies. The latest plan has three distinct characteristics: (1) Lake, reservoir, river and canal of irrigation were delineated, each being an element. The hydrological cycle plays a significant role. Evaporation and percolation from such openings; for example, water bodies can be essential and must be quantified accordingly. (2) There have been found some vegetation at the stage of the organisms. The regional water balance can be analyzed as followed in equation (1).

$$Q + R_{in} + M_{in} = ET + Rout + M_{out} + \Delta A + \Delta MW + \Delta C + \Delta N \tag{1}$$

When Q is rain; Rin is an inflowing stream; Min is an inflow of soil water, ET is evaporation; Evaporation (E) and sulfur (T) can be broken down. Rout is a stream outflow, and Rout is groundwater Outs low.

Where ΔA oscillating the soil water, ΔMW is the oscillating the soil water storage is oscillating, ΔC is the modification of the storage of cryospheric water, and ΔN is the lake's modification of the storage of water in the tank. Improvements and storage declines lead respectively to positive and negative values. In the upstream HRB mountainous region, there is no inflow and the $-\Delta N$ can be ignored.

The water balance is thus simplified in the upstream HRB region as shown in equation (2)

$$Q = ET + R_{out} + M_{out} + \Delta A + \Delta MW + \Delta C \tag{2}$$

It measured liquid precipitation (rainfall) and solid precipitation (snowfall) for P. The path can be extended. The surface (Ds) and base flow (Db) are decomposed as followed in equation (3)

$$R_{out} = D_S + Db \tag{3}$$

Another approach is to decompose the outflow of the stream into components from various sources, the snow melting (Dglacier) and glacier melting require the rainfall (Drain) are described in equation (4)

$$R_{out} = D_{rain} + D_{snow} + D_{glacier} \tag{4}$$

In equation (4) increase in performance is determined with R_{out}. ΔC can be ignored in the Midstream region of the HRB. The water equilibrium, area midstream may be expressed as shown in equation (5)

$$Q + R_{in} + M_{in} = ET + R_{out} + M_{out} + \Delta A + \Delta MW + \Delta N \tag{5}$$

In equation (5), the community-based ratio is increased. No outflow of streams and groundwater is available in the HRB Lake terminal's downstream region or sink in the desert. Then, it can convey the water balance are expressed in equation (6)

$$Q + R_{in} + Min = ET + \Delta A + \Delta MW + \Delta N \tag{6}$$

From equation (6) the efficiency has been increased. The following equation (7) is used in the river basin's water balance—no endorheic basin outflows.

$$Q = ET + \Delta A + \Delta MW + \Delta N + \Delta C \tag{7}$$

The units of the above quantities may be either a flux unit or the total amount. Flux unit is more important while calculating the water balance process.

3.3. Case 2 environmental analysis for resource management

Economic activity depends on the earth's portion and the composition of the atmosphere. The system is known as a 'natural world' and has the remaining atmosphere of the universe. The interdependence schematics, two-way relationships and the economy are shown in Figure 170.2. The external sizeable black box is the thermodynamically closed setting system by sharing energy; however, not its surroundings matter. Sun radiation inputs sustain the environment is absorbed and driven by environmental processes. The intense black doesn't shift across the issue. The balance between absorption of energy and the way the global climate is established functions of the system. The strength of the arrows is seen in three boxes reflecting in Figure 170.3. The temperature and production
Figure 170.2. Water balance analysis.

Source: Author.

and consumption are dependent on the environment services, as evidenced by strong lines inside. Loud box lined. All production does not consume it. Some of the output is added in the production—the capital stock of individuals, reproducible and manufacturing tools, following jobs services. Production is shown in Figure 170.3, resources derived from the third type of input. Consumption uses a flux of amenities directly from environmental programs to people without constructive operation intermediation.

3.4. Applying of material balance principle

The phrase 'principle of material balance' is the economists tend to use mass conservation law to facilitate states the matter cannot be respected. Early exposure to economic activities' theory is established concerning the economy—the materials' most fundamental presence. The idea of balance is how economic activity fundamentally involves transforming climate content of the environment. Economical operation is unlikely in creating something, material meaning. Naturally, it does, include material derived from the transformation climate to make it more precious to people.

The physical ties show in Figure 170.4 implicit in the concept of material harmony. It abstracts from the circular matter flow lags because of the economy's capital accumulation. It amplifies the image of extractions of material from and the insertions provided in
Figure 170.3. Environmental activity concerning resource management.

Figure 170.4. Material balance between environmental and economic.

Source: Author.

the environment. Main inputs (ores, liquids and gases) are removed and transformed from the setting—utility goods (essential fuel, food and raw materials).

The above Figure 170.4 shows how the economic and environment is connected through material balance principle for managing sustainable Natural Energy resource management. It was explained through the below-mentioned equations.

The environment $E \equiv F + G + H$ as above, the environmental Firms such as $B = B1 + B2 + C$ Non-environmental firms such as $C + Q + R$, in equation (7) F, G, H is represented as a mass of fuels, foods and other raw materials. While microeconomics production is considered in equation (8)

$$Ri = fi (Mi, Ki) \qquad (8)$$

The R represents an output, M is a labour input, and K is a capital-output. Ri is an otherwise material element. In the above equation (8), the cost has been increased.

$$Ri = fi (Mi, Ki, Ni) \qquad (9)$$

In the above equation (9), disagrees with it stands the theory of equilibrium of materials. Now, the problem is regarding economic activity and the cause of waste. It was not possible alone. A summary of resource and development functions in the environmental economy with resource management. It is desirable to the material inputs are recognized with the role of production and output of materials (format). The show emanates from waste and production. The results in a production feature are shown in the below equation (10)

$$Ri = fi (Mi, Ki, Ni, Oi (Ri), A [\Sigma Mi]) \qquad (10)$$

The equation (10) describes the waste emissions would be avoided by calculating the mass production of materials.

3.5. Quantitative analysis

Figure 170.5 shows the various elements linked to environmental and economic factors. Data analysis is conducted by the integration of qualitative and quantitative analytical data. In other words, the steps quantitative analysis is too used for qualitative research at the same time. Data is interpreted or analyzed, reducing it, in particular for qualitative categorization of data. Descriptive mathematical calculations and quantitative data are carried out. Then are the two data or between methods conducted triangulation. It means how a questionnaire is used to collect data. Two approaches, qualitative and quantitative, need to be discussed further. It fusion is more enhancing the validity of the empirical findings.

The effect of the environmental impact is shown in equation (11) as follows:

$$X = b + C1Y1 + PYX2 + b3X3 + \ldots + bnXn \qquad (11)$$

In the above equation (11), resiliency is decreased. Besides, path analysis applies to variables (i) Y1 independent, exogenous (Natural Energy resource preservation) exogenous variable, (ii) (economic empowerment), (iii) X3 exogenous independent variable (community capacity building), (iv) Y endogenous variable dependent (economic enterprise productivity) and (v) f1 endogenous variable endogenous dependent variable (ecosystem sustainability) are shown in followed equation (12)

$$Z = QXY1 + QXY2 + QXY3 + f1 \qquad (12)$$

Figure 170.6 shows the structural equation. The path analysis is used to take account of the interval (ii) of the exogenous and endogenous dependent variables reference to multiple regression models in the measurement of metric study data, and (iii) of the intermediated variables reference a mediation model and multiple, complex models of mediation and regression; and (iv) of the relationship between these variables.

The research aims to improve resource management without wasting any resource while using Heuristic Sustainability Natural Energy resource Management (HSNRM) approach. They display

some characteristics regarding the accurate statement: community-based analysis, performance, cost, accuracy and efficiency results of Natural Energy resource management.

4. Results and Discussions

The successful findings were shown by environmental analysis and are linked to recent developments through sustainable strategies and various factors. The different modelling approaches were used for analyzing the effectiveness of Natural Energy resource management process. The multiple population details and foreign policies and procedures are too established to show resource management effectiveness. The community-based analysis involves community stakeholders, representatives of the organization, researchers, and those with experience and decision-making and ownership sharing from all process partners in each aspect of the research process.

Table 170.1 shows the survey year and the number of clusters and the number of person lifestyle for managing the Natural Energy resources. Evaluation of management output is central to the management of Natural Energy resources to enhance an integrated learning cycle's successful intervention. It's not easy, since these processes have many interactions and response scales in general. The frequency of deformations, uncertainty and the difference in time is high. Five assets are recognized in either approach: physical, economical, social, natural and human. Many principles can be extracted for each capital asset; metrics should protect all system performance assessment principles. Participatory selection of indicators is sufficient for multiple stakeholders, although specific generic hands are adequate when cross-site comparability is necessary.

Decision-makers surveyed schedules to predict nitrogen and carbon management activities considered the forecasts for 1 to 2 years were most beneficial.

Table 170.1. Performance ratio analysis

S. No	Survey Year	Number of Groups	Observations Made
1	2008	129	Natural Gas
2	2009	213	Coal
3	2010	320	Air, Water
4	2011	350	Soil
5	2012	365	Natural Gas
6	2013	380	Coal
7	2014	420	Air, Water
8	2018	500	Soil

Source: Author.

The second most useful time frame chosen in nitrogen management decisions was days-12 months, while the second most helpful time frame selected for carbon management was 10 to 150 years. The disparity may reflect the fact to patterns of transports and deposition of nitrogen change on a seasonal basis. On the other hand, relevant time scales are about decades to centuries for decision-makers interested in agricultural soils' potential carbon sequestration. Figure 170.7 performance analysis is high compared to existing methods CBNRM, LSD, and GFN, NRBV.
Figure 170.7. Performance analysis.

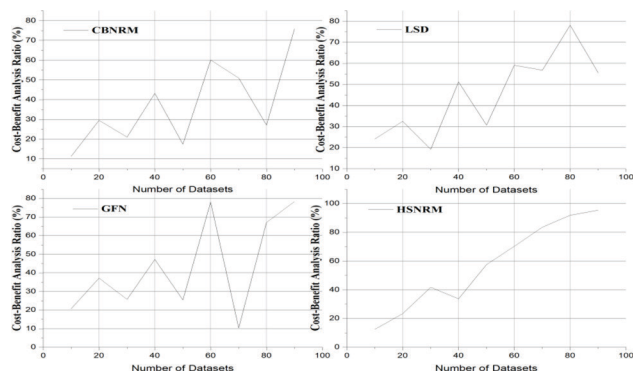
Source: Author.


Figure 170.8. Cost-benefit analysis.

Source: Author.

The above Figure 170.8 shows the cost-benefit analysis measurement using some environmental factors. The cost ratio is a systematic method in which costs and benefits are defined, measured and compared. To decide whether a project's advantages outweigh its costs, and how much in conjunction with other alternatives. It determines whether a sound decision or investment is (or was) a proposed project. The cost analysis method is based on the basic principles of social protection economics (Economics to consider society's well-being). The use of the cost ratio as part of public decision-making processes is widely accepted. Instead of a single individual or interest group, costs and benefits are measured from an aggregate perspective.

The efficiency of energy means sustainable use of earth's finite resources. They rely on Natural Energy resources metals, minerals, fuels, water, land, wood, soils, clean air and biodiversity for our survival. Considering sustainability and environmental effects save help in every possible way and location recycling and reuse increasing internal reuse and recycling of materials and product components. Economic efficiency indicates a financial state in which all resources are best used for every person or organization, thereby eliminating waste and inefficiency. Economic effectiveness implies economic efficiency. Any adjustment made to support one organization would hurt another if an

90	73.54	76.65	71.47	73.61	97.45

Source: Author.

economy were economically productive. The above Figure 170.9 efficiency means a maximum performance that uses the lowest input to produce the highest output. Reducing unnecessary resources used to generate a given outcome, including personal time and energy, requires understanding in Table 170.2.

The proposed method for assessing Sustainable Natural Energy resource Management effectiveness is illustrated in Table 170.1. It means optimal output using the lowest input to generate the highest performance. The comparative research outcome suggests that the efficiency rate is 73.54%, 76.65%, 71.47%, 73.61%, 97.45% for CBNRB, LSD, and GFN NRBV and HSNRB. The research still presents a better approach, as with the resource management system; there is an improved efficiency rate of 97.45 per cent.

Figure 170.10 defines adaptation's mechanism to respond well to hardship, trauma, disaster, threats, and significant stress factors—for example, family and relationship issues, severe health problems, working conditions, and financial stressors. It was resilience's function. Resilience is vital because it gives people the strength to resolve difficulties. These people lack stability and can resort to dysfunctional coping strategies. Resilient people use their talents and systems to solve obstacles and cope with problems. The depletion of human stressors in lowland wetlands continues with more minor, scattered and climatic stressors, thus reducing their resilience. Overall, human stressors will be increased, and the ecological roles and efficiency of fresh and salty lakes will continue to be diminished, resulting in lower resilience.

5. Conclusion

This review shows the conceptual framework of social learning and political learning theories, transformational learning, etc. They explored how each theory's underlying assumptions, who learns and how learns
occur, form perceptions of the types of outcomes and broader consequences of the learning process. In the literature on NRM linked to learning, conceptual diversity needs to be discussed in future transformational change studies. There is a need for a unified vocabulary across multiple theories, leading to a more accurate comparison between interventions and processes evolving, learning results and their ties to transformative NRM change. Our analysis makes a minor contribution in either direction in highlighting these disparities.

The complexity of Natural Energy resource use, agriculture and rural development at international, national and local levels needs sustainable strategies. The sustainable process needs to take a more systematic, Heuristic Sustainability Natural Energy resource Management approach to understand these problems. Systems thinking are necessary to help us collectively think and learn how to deal with this difficulty and challenge. The simulation results show the Heuristic Sustainability Natural Energy resource Management approach achieves 95% community-based analysis, 98% performance analysis, a 96% cost, a 13% resiliency, and a 97% Efficiency in representing the Natural Energy resource management.

Abstract: In order to identify the *peroxidase* genes in Indian bael plants, we are retrieving and characterizing the *peroxidase* genes in model plants. Materials and Methods: *Peroxidase* genes from model plants Arabidopsis, poplar, rice and citrus are retrieved through the Phytozome website. Through online software we predict the proteins' physicochemical property and domain organization. Using the MEGA software, a phylogenetic tree was created to determine the evolutionary relationship between the various genes. Result: A total number of 29 peroxidase gene sequences from different plants were retrieved from the 4 model plants through the phytozome website. Phylogenetic analysis has shown that the tree plant spp gene sequences fall under the same clade while rice and arabidopsis fall under different clades. *In silico* analysis of *peroxidase* gene families showed that protein exhibits peroxidase domain. Conclusion: The various physico-chemical characteristics of the *peroxidase* genes found in the model plants are examined in this research. Furthermore, the structural analysis of the protein has demonstrated that the selected proteins all contain peroxidase and peroxidase-related domains which could confirm that they are true *peroxidase* genes.

Keywords: Peroxidase, Reactive oxygen species (ROS), arabidopsis, H_2O_2, phytozome, antioxidant, stress condition, pollution

1. Introduction

Plants are continuously exposed to biotic and abiotic stress conditions and pollution which generate the Reactive Oxygen Species (ROS). ROS is composed of different reactive molecules and H_2O_2 is one among them. Excessive ROS production damages the plants by denaturing the cellular protein, lipids and DNA [3]. ROS production is necessary for the plants during the various developmental stages as it acts as one of the important signaling factors to activate many genes and transcription factors expression (Huang 2019). Thus there is a need for a system to regulate the ROS production in a controlled manner. In plants many antioxidant systems (enzymatic and non-enzymatic) regulate the ROS production. One among the antioxidant machinery is the peroxidase that is highly engaged in the scavenging of ROS production. The reaction mechanism of H_2O_2 reduction is similar to that of peroxidase and it widely depends on the type of substrate used. Peroxidase is able to oxidase a wide array of organic and inorganic substrates. Catalyzing the oxidoreduction reaction between hydrogen peroxide (H2O2) as an electron acceptor and various electron donors, including auxin, phenolic compounds, or secondary metabolites, peroxidases are a vast family of enzymes that are extensively dispersed in living organisms.

This work has been the subject of more than 2000 publications on PubMed and Google Scholar.

Peroxidases gene family is a multigenic gene family and are classified into two classes (heme-peroxidase and non-heme peroxidase) based on the presence of heme-containing cofactors. Greater peroxidase levels suggest more extensive generation of harmful hydrogen peroxidase resulting from reactions between various kinds of green plants. peroxidases that are involved in the physiological reactions of plants to biotic stress, drought resistance, and disease [1, 7, 16] peroxidases are involved in polymerization of precursors of lignin. It has been extensively employed as a genetic marker in the study of genetic diversity, plant growth and development, and plant variety identification [15, 18, 19, 21]. Enzymatic browning may result from the interaction of phenolic substance enzymes with oxygen [6]. Plant enzymatic browning is caused by the enzymes superoxide dismutase, peroxidase, and polyphenol [4]. According to Beklen et al. [2] and King [8], peroxidase is the primary gene responsible for enzymatic browning in model plants. Reduced lignification levels in etiolated plants may be associated with reduced peroxidase activity. Heme factors are present in peroxides, which are primarily heme binding proteins. Peroxides primarily represent the traits of plant growth and development, including their capacity to adjust to environmental changes and genetic variations. Peroxidases are involved in lignin production, among other physiological activities in a wide variety of plants. A diverse array of classical peroxidases is present in higher plants. (class III peroxidases). Numerous physiological processes in plants, including H2O2 detoxification, auxin catabolism, lignin biosynthesis, and the stress response (in reaction to injury, infection, etc.), have been linked to these enzymes. Plant peroxidases have a variety of roles in the growth and development of plants during the course of their lives.

Recently, an electrochemical based detection technique has been developed to study plant activity of peroxidase [11]. Peroxidases can catalyze hydrogen peroxide determination of plant sex. Lignin is a polymer that helps make cell walls hydrophobic and makes plants stronger and more rigid. This is a low cost method for detection of peroxidase genes in model plants. A number of molecular biology techniques have been developed in the past ten years to isolate, characterize, and investigate plant peroxidase gene expression. Numerous genes producing peroxidase have been found in A. thaliana since the initial genes were characterized thanks to the various expressed. The peroxidases are secretory enzymes that are located in the vacuole or extracellular space. They are members of class III of the plant peroxidase superfamily. They have a signal peptide that is required to route the endoplasmic reticulum, and some of them also have a C-terminal extension, which has been demonstrated to be responsible for the vacuolar

targeting of some plant proteins [5]. Phylogenetic classification includes many forms of peroxidase it includes pathogen resistance in plants. Class III peroxidases are the secretory enzymes present in ubiquitous multigene Plant families have been found to play a significant role in various plant species, including Arabidopsis thaliana [73 genes] [13, 22]. Oryza sativa [138 genes] peroxidases widely present in model plants and plays an important role in many physiological functions Class III peroxidase are present in all land plants. The peroxidase superfamily is divided into three structural classes and also there are two classes of heme peroxidases in plants Class I peroxidase main function is to detoxify excess H_2O_2 Class III peroxidases mainly found in terrestrial plants it contains N-terminal signal peptides [9] and plays major role in cell wall modification it is involved in detoxification of hydrogen peroxide it is involved in lignin synthesis, pathogen defense, and the oxidation of toxic reductants peroxidase in rice and environmental factors and pollution has minor effect on isozyme patterns. Peroxidase are heme containing oxidoreductases and can oxidase various hydrogen donors [17, 23].

2. Materials and Methods

2.1. Software

Phytozome, a plant genome database portal for plant genomic sequences was used for retrieving the sequence. From this website, we can select the peroxidase gene sequences for model plants such as *Arabidopsis thaliana, populus Trichocarpa, Oryza sativa* and *Citrus Sinensis*.

In the Phytozome site, search was initiated using the key term peroxidase to search against the model plants' genome nucleotide gene sequences and protein sequences for genes. The sequences are retrieved in FASTA format. Through the Expasy site—the pI/Mw of the protein were predicted. Using MEGA 5.1 software, a phylogenetic tree was built for the given sequences using the NJ method and a bootstrap value of 1000. For the multiple sequence alignment, it was aligned using the CLUSTAL W site available on the EMBL site and then and then aligned and colored using the JAL view programme. The domains present in the protein are predicted using the web programme MOTIF: Searching Protein Sequence.

Using a JTT matrix-based model and the Maximum Likelihood approach, the evolutionary history was deduced. The displayed tree has the highest log probability (-16821.09). After applying the Neighbor-Join and BioNJ algorithms to a matrix of pairwise distances calculated using the JTT model, the initial tree(s) for the heuristic search were automatically generated. The topology with the highest log likelihood

value was then chosen. There were 29 amino acid sequences in this investigation. The final dataset contained 678 locations in total. In MEGA11, evolutionary analyses were carried out in Table 171.1.

3. Results

3.1. Identification and multiple sequence alignment of peroxidase gene families in model plants

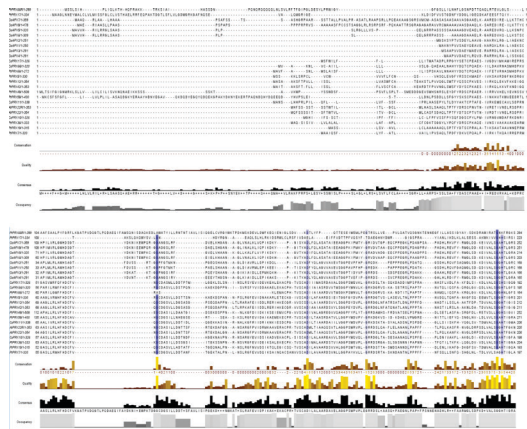
We have discovered 2 *peroxidase* genes from Arabidopsis, 15 genes from poplar 4 genes from rice plants and 4 *peroxidase* genes from citrus plants as a result of our study. For all three plants, the size of the genes is different in Figure 171.1. The Molecular weight of the proteins fall between 80 to 90 kDa. There were only 4


Figure 171.2. The chosen peroxidase protein sequence from each of the four model plants was aligned several times. Arabidopsis, Poplar, and rice. The regions which are showing similarity are shaded with color. Maximum identity exists among the selected peroxidase proteins they show high similar sequences. The alignment has shown that the protein sequences share high identity to each other. By setting the 100% as the identity value for proteins more than 70% of the proteins show the identity.

peroxidase genes found in citrus plants. The four genes are present in Arabidopsis as isoenzymes, and they are most similar to one another. The pH level at which a protein is regarded neutral and has no net electrical charge is known as the protein's isoelectric or isoionic point. In order to build buffer systems for purification and isoelectric focus, the prediction of pI is necessary.

3.2. Phylogenetic analysis of the selected protein

The chosen *peroxidase* genes were placed on an unrooted phylogenetic tree, which was divided into

Source: Author.

four groups, to explore the evolutionary links which were clustered into four groups. Different model plant species' peroxidase genes showed both orthologous and paralogous relationships with one another. This suggests that this gene family has developed from ancestral plants and is strictly conserved.

3.3. Domain organization of the selected proteins

Using sequence motifs identified by protein sequence analysis, the potential activities of specific enzymes can be determined in Figure 171.2 [20]. The chosen protein's domain organization was looked at using the online application. The research shows that the organization of protein domains is universal in Figure 171.3. Plant peroxidase' predominant proline content in their amino acid profile may have contributed to their coiled-structured protein. Proline has the rare ability to force polypeptide chains to coil because it disrupts secondary conformations. All the chosen proteins had a peroxidase immune-responsive domain, the domain analysis of proteins showed.

4. Discussion

As a byproduct of many oxidases and superoxide dismutases, hydrogen peroxide is dangerous on its own and can combine with Fenton-type catalysts to produce the much more reactive hydroxyl radical. Among oxygen's active intermediates, this radical is most likely the most dangerous since it interacts with surrounding lipids, proteins, and DNA [14]. There aren't many genes in the plant gene family. The comparative genomics study provides strong support for the theory of plant peroxidase gene function [10] and evolution research by improving our understanding of functional genes within and between plant species.

In Silico protein structure analysis is a highly helpful approach for evaluating protein structure-function correlations [12] when the crystal structures are not accessible. In analyzing the structure-function relationships of proteins, In Silico protein structure analysis is a very useful technique because it can often be difficult to get structural data due to the shortage of crystal structures.

5. Conclusion

We were able to identify peroxidase genes in four model plants, including Citrus sinensis, Oryza sativa, Arabidopsis thaliana, and Populus trichocarpa, based on the results of the current study. The phylogenetic analysis shows that the protein form four different clades. Identification of the domain organization will help to identify the specific cofactors that interact with the protein. The physico-chemical characteristics analyzed for the model plants *peroxidase* genes will be helpful to identify and annotate the *peroxidase* genes present in *Aegle marmelo*s.

172 Representation of entrepreneurs success and failure in a sustainable energy sector: A case study

Byju John[1,a] and Nitin Ranjan Rai[2]

[1]Professor, Department of Management, Kalinga University, Raipur, India
[2]Department of Management, Kalinga University, Raipur, India

Abstract: The proposed paper explores the mechanisms and causes of interconnected sustainable energy sector' success and failure to become a competitive, valuable business model for their network ability participants. The article discusses four different initiatives in the case study network: the new entrepreneur's network has failed informally, a robust informal group of local clusters, a failed network of authorized defence contractors, and a competitive small-scale professional community of businesses. Sustainable energy sector in the industry are created and managed actively by managing directors who understand the value of collaboration to achieve a strategic edge for their companies. The best service for the network is the traders, who can combine and balance the participants with hard business and social desires. Case studies show that structured groups are the most potent type of a cross-company network, and they are best handled by an Entrepreneurial Optimization of Adversarial Framework. It is assumed to facilitate the businesses' incentive to become active in these sustainable energy sector involves both economic and social rationalities. Their performance is closely related to the current similarity between participants. The simulation results show the Entrepreneurial Optimization of Adversarial Framework achieves 97% accuracy, 98% performance, 95% success rate, 94% failure rate, and 99% market outcome in representing the success and failure with the sustainable energy sector.

Keywords: Business, entrepreneur, success and failure, EoAF

1. Introduction

It represents the correct attitude to a company and the desire and commitment to succeed. Whether it is the evolution of ideas, services, goods, or technology, the road to success lies in development. What effectively makes an entrepreneur is passion, money, the desire to improvise and listen to others and a powerful will to succeed. However, research shows to, within five years of their company, the failure rate for new companies is close to 50% [12]. It takes much time, money, and effort to start a company, and failing or even going bankrupt is the last thing any business owner would want to do with their business [15]. The aim is to create trust and inspire each other to achieve objectives [18]. The main contribution of the research is Improve the success and failure of the entrepreneur who can participate in the network's survival. The suggested solution to links the various features to compete with

the small-scale business community is the Entrepreneurial Optimization of the Adversarial System. The paper is structured as follows: Section I addresses the Introduction of Success and Failure of Entrepreneurs, followed by a detailed Literature Review in Section II. A complicated mathematical equation of the Entrepreneurial optimization of the adversarial framework is concerned with section III.

2. Literature Review

To demonstrate how entrepreneurial ecosystems are evolved and to create a typology of different structures and frameworks of ecosystems. The Dynamic Start-up Business Model was introduced by Federico et al. [22] to evaluate complex processes and facilitate the creation of creative strategies. Diaspora entrepreneurs in Start-up Ecosystem Development is proposed by Baron et al. [23] It investigates how the singularity of

diasporas companies will help start-ups build a competitive ecosystem. It was found in Berlin and Diasporas to improve the ecosystem's capitals and serve as broad "interweaves" between such media and the Berlin start-up ecosystem's particular and competitive structure. A gendered perception of entrepreneurship ecosystems was explored by Brush et al. [24] Ecosystems of entrepreneurship are an implicit expectation and all entrepreneurs have equal access to capital, involvement, and encouragement, as well as equal opportunities for a good outcome. A financial crisis threatens the organization's continued sustainability, except it can be seen as a step to reassess and reassemble resources to meet future market requirements. And it takes place either through a reorganization supervised by the court or by informal reform without the courts' intervention. Gyimah P et al. [26] proposed to test the Lussier model's validity to forecast small business performance or loss in a Success versus a Failure Prediction Model. The Lussier model's relevance as a global performance model or failure prediction leads to theory and practice. Entrepreneurial optimization of the adversarial framework is proposed, and its approach interconnects the different characteristics of the small-scale business community.

3. Entrepreneurial Optimization of Adversarial Framework

The proposed system's design purpose requires both economic and social rationalities, and their success is closely linked to the present similarity between participants. It is suggested with an informal approach to long-term Entrepreneur Framework outcomes including impacts on the failed entrepreneur, the failed entrepreneur's potential and present organization, and the failed entrepreneur's external climate. However, it is assumed when the proposed approach to long-term entrepreneurial failure outcomes supports and expands previous considerations about company failure results. Because most research does not distinguish between individual and organizational levels when addressing entrepreneurial failure theory, some paper to find it distinction, particularly studies focused on exploring learning-related effects, is a significant starting point in their research. Although there is a large amount of research on entrepreneurs, reviewing the literature and most of the work done in research regard revealed to the authors concentrated on the various aspects of success and failure of entrepreneurs. It offers evidence of how the Entrepreneurial optimization of the adversarial system will impact the loss of entrepreneurship. Therefore, the Informal Entrepreneurial Failure Effects Paradigm provides a comprehensive and systematic view of the entire entrepreneurial failure mechanism, including multifaceted triggers, incidents, and various

effects. An Entrepreneurial optimization of the adversarial data for testing was based on critical online variables. Developers developed a system based on the literature of study, Full Quality Management theories, entrepreneurial ideas, and exploratory interviews with knowledgeable officials and entrepreneurs.

As shown in Figure 172.1, entrepreneurs need to build a business model, whether beginning a new company, expanding into a new market, or updating market strategy. It can use a sustainable energy structure in one position to capture simple expectations and choices about the opportunity, setting the course for success. A product is a customer's tangible bid, while a service is an intangible offering. Generally, the former is a one-time trade for value. Networking is sharing information and ideas between people with a typical career or a particular interest, usually in an informal social environment. Networking of computers refers to the linkage of many machines to enable information and easily share computing resources. An 'entrepreneurial network' is a structured group of entrepreneurs, formally or informally, to increase the participants' business activities. The Entrepreneurial optimization of the adversarial framework Method must execute both economic and social rationalities closely linked to the present similarity between participants.

As shown in Figure 172.2, the successful entrepreneurs were defined based on the operational concept. A good plan can be easily shared with those concerned and is very useful when frequently revisited.
Figure 172.1. Entrepreneur business model based on the informal system.

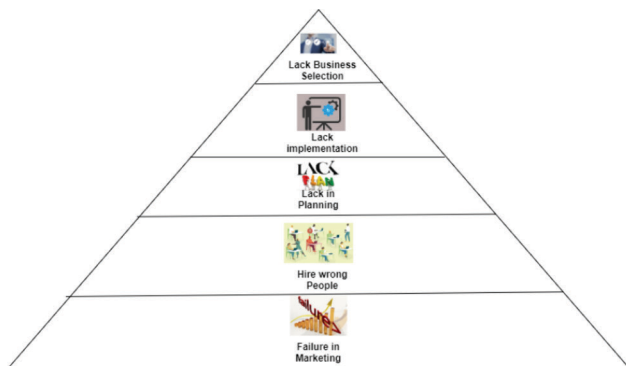
Source: Author.

Figure 172.2. Entrepreneurs success rate.

Source: Author.

The "research and development" of the entrepreneur himself is the largest source of new ideas. Everyone is inherently conscious of something happening when teams are small, and meetings can be ad hoc. However, as to expand, adding structure and creating a reliable team standard is a good idea. Recall how sessions break productivity up and attempt to take a lesser role while preparing daily touchpoints for the team. The item offered for sale is a commodity. A service or an object may be a commodity. A market is a place where it is possible to meet two parties to promote the exchange of goods and services. Both economic and social rationality is involved in these sustainable energy sector.

Figure 172.3 shows the entrepreneurs failure rate. From the point of view, companies' choice is one of the key reasons many businesses struggle. Anyone who decides which company should change is one of the tricky times of business life. Without proper implementation, a master plan is worth nothing. The failure to execute there are many causes; however, inadequate management is the most significant one. Implementing new strategies poses tremendous challenges; leaders must be brave and committed, and patient. Another frequent cause for companies to fail and exit the market is improper preparation. For the first time, many entrepreneurs sometimes miss how a business plan is essential to start a new business. The right people are critical to any entrepreneur's success. The recruitment of a wrong person is a waste of money, and a hostile working atmosphere does not positively sign. Marketing plays a critical role in any company's success as well as being a significant factor in the entrepreneurs' failure.

Let S denote a space, XY (net new development of jobs/age 0 company) >XY (net new development of jobs/established company). XY (new Entrepreneur job formation at the finish of the job) in F-space, Time in Business Entrepreneurial) > XY (new business job network) establishment at the end of one business cycle).


The sum of job formation, meanwhile, with time, is inevitably subject to a decline in S-space, there is no restriction of its sort in F-space. In the case of an entrepreneur of one time (where F-space either businesses or jobs are short-lived, or, to the extent they thrive, the fewer net new jobs they bring to the economy, they fall into S-space.

Three requirements must be fulfilled for Informal Entrepreneurship to exist throughout the career of each serial entrepreneur: (1) The rate of firm Failure should be less than 100% (2) Firm Failure does not inherently mean company failure (3) A minimum number of accomplishments, for example, should be necessary for Q off from H attempts to ensure market success. The first state guarantees the viability of entrepreneurship. The second and third conditions aim to secure the viability of seriality. It follows from the second condition to facilitate $XY(Vl > I)(1 - Y)$ the threshold be Q\H. Every result is either a performance (S), with a constant value of R (conditioned firm failure rate), or success with a possibility of $X = 1 - Y$ (F). The central importance of two random variables is followed in equation (1)

Ui = number of trial successes in i;

Vl = number of trials failures in l achievements.

The primary character in which the two variables are related is:

$$XY(Ui + l) = XY(Vl > i)(1 - Y) + XY(1 - X)(Vl < i) \tag{1}$$

Figure 172.4 shows the variable declaration. For example, if at least three successes have been selected, a contractor must be qualified to succeed. For a specific contractor, the series of tosses is FFSFFSFS. In this case, then $V_l = 0, 1, 2, \ldots n$, $U_i = 0, 1, \ldots n+1$ or equivalently.

The above identity 'explanations' why the entrepreneur is in a serial business; it is essential. Supposing i = 1 to And the Y = 2 threshold then it denoted in equation (2)

$$X(\#(Failure) \text{ in } 10 \text{ trials} < 2) = required\ XY(\#(trials) \tag{2}$$

Figure 172.3. Entrepreneurs failure rate.
Source: Author.

Figure 172.4. Variable declaration.

Source: Author.

In the above equation (2), X(#(Failure) in 10 trials<2) which the serial entrepreneur's risk of failure. Another way it can be done is to ensure that the problems are not separate, other than facilitating they are linked in such a way to success in one test is more likely to be expectations hit. Higher levels of firm loss can be increased if success is contagious. The study uses mathematical literature results mostly off-the-shelf, and comprehensive derivatives were avoided, where possible.

If there is a minimum of Y achievements based on the ability to declare an accomplishment for the entrepreneur, then it represented in equation (3)

$$f(Vl) = XY(Vl - l) = X\left(1 + \frac{l}{i}\right)^{il} \tag{3}$$

i = X, X+1, X+2, ...

As shown in equation (3), where l = 0, 1, 2, ... n+1.

If the contractor A maximum of j > Y trials, the cumulative trials, is given. The system of correlated allocation of XY and l based on the previous VI is described with the above. In the above analysis, the solutions for the research are presented 1 + l/i. Is identified to detect the success and failure rate. The order of conditions f (j,Y) = 1, V = n, Q = 1, is given. The first solution is optimal and therefore does not require any Attuning when the solution is solved in equation (4)

$$f(j,Y) = \sum_{v=1}^{\infty} (v + Y/2) = \sum_{v=1}^{\infty} (v - Q/2)XY$$
$$= \sum_{v=1}^{\infty} \left(\frac{u}{2} + Q\right)XY(li) \tag{4}$$

Equation (4) is represented by measuring success and failure performance (v + Y/2). is determined to identify the maximum instances and (v + Q/2) XY to measure the minimum instances (U/2 + Q)XY. Determine either success or failure of an entrepreneur. Seriality amplification (and the concept of entrepreneurial performance) is the ratio of the likelihood of entrepreneurs achieving j achievements in most Y Probability trials in one experiment for success (determined by the rate of firm success) in followed equation (5)

$$f(j,X,Y) = \frac{f(j,Y)X}{2}$$
$$= 1 + f(Xl) \sum_{i=0}^{l} \binom{l}{i} X^i j^{l+i} \tag{5}$$

Here (j,X,Y) output of regression is determined with f (j,Y) correlation function and X, a variable. $X^i j^{l+i}$ is the computed sequence to define the performance, and f(XI) is an access parameter integrated with version is showed in equation (6)

$$\frac{a(j,X,Y)}{1-\alpha} \leq \text{amplification } (j, X, Y) \geq a (j, X, Y) \tag{6}$$

As inferred from the equation (6), a primary concept and an approximation result can be attached to the two input term.

If, for instance, Y = 2; X = 0:1; j = 6, then X = 0:1; j = 6. As a consequence of seriality, the amplification factor is limited, then its shows in equation (7)

$$1.3458 \leq amplification(j, X, Y) \leq 1.9856 \tag{7}$$

In some situation, seriality would have an amplification Increase by anywhere from 34 per cent to 82 per cent over the rate of firm success.

As before, the distribution function for the event is the item of interest VY = i.

It is not entirely impractical, considering the limited logical nature of other simplification: human beings and resultant myopia on how history has influenced new possibilities.

Let , represent the probabilities of results and in every single trial, loss. Then it is possible to write the transfer probabilities as described in equation (8)

$$f(j,X,Y) = \binom{XY(R_{s+1} = B)}{XY(R_{s-1} = B)}\binom{XY(Q-1)}{X(J-1)} \tag{8}$$

As shown in equation (8), where Q > X is without good breed success, it is impossible to have" failure to breed failure'. Notice whether, for XY, any increase (decrease) in (Rs+1 = B) often increases (decrease) in XY (Rs-1= B) and XY(Q-1) is denote the level of technology. The Entrepreneurial optimization of the adversarial model, as introduced, is the starting point for our framework. And it represented in the following equation (9)

$$G = H \propto .M\beta.(N.O)1 + \alpha - \beta G \tag{9}$$

Figure 172.5 shows the informal if H = M, where G denotes the gross domestic product. (Physical) capital input and labour are denoted by H and O (measured in mathematical terms, including business hours). M represents human resources, with N representing Shift's degree in technology (to raise labour). From the equation above, It can be extracted from the following labour productivity equation is solved in equation (10)

$$GO = N1 + \alpha(HO)\alpha.\beta \tag{10}$$

Labour productivity relies on the ratio of capital-labour (HO), human capital per labour unit. (GO),
Figure 172.5. Informal if H = M.

Source: Author.

and the technology degree is captured by the pressuring $(1-\alpha+\beta) \ln(N)$. Residually, the total production factor (TFP) level represents how efficient the production factors of capital and labour are combined to produce added value. Estimate the $\delta = 1.224$, $\beta = 0.071$, and γ values at 0.4501818 ensures the conjoint function. Replace Ţ, β and β coefficients in the equation, which are approximate is explored in equation (11)

$$lT(GO) = (1 - \alpha + \beta)lT(N) + \alpha lT(HO) - \beta lT(HO) \qquad (11)$$

It is difficult to test empirically endogenous growth models from a theoretical perspective. It is worth noting these models' intentions are focused on creating global knowledge, making them less useful for implementation at a national level. The equation (11) above has derived in equation (12)

$$\Delta lT(TotalFactors) = \Delta lT(GO) - \omega^H \Delta lT(Go) \qquad (12)$$

In the system to render them less useful at the country level, these models' goal should be remembered as focused on knowledge production functions at the world level. However, the residual term represents the degree of TFP, which measures how efficiently the capital and labour output variables are combined to generate added value. The values of Δln (Total Factors) relative can be determined for the total productivity index.

Figure 172.6 shows the informal variable ω assigned. Here the proportion of income capital in total factor income is H, by if not specified, in gross domestic product the Capital income has balanced. Subsequently, by summing the values at ΔlT(TFP) relative to a base, a total productivity index can be determined. And weights are denoted in equation (13)

$$E^Z = BCZ + (1 + \delta)E^z + 1 \qquad (13)$$

In equation (13) represents the cross-validation, E^z measured with the entrepreneurial factor BCZ and. GDP per capita is new to correct entrepreneurial growth for time and region, and a U-shaped type is
employed. The equation (14) has derived from the following above equation (13)

$$A^\wedge = \delta + \beta XSAP - \gamma XSAP(\tfrac{BC}{N} + 1)(\tfrac{ZSAP}{N} + 2) \qquad (14)$$

The 'standardized' number of business owners per labour force is A^, and GDP per capita is expressed by the market outcome, XSAP with entrepreneur factor. Estimate the $\delta = 1.224$, $\beta = 0.071$, and γ values at 0.4501818. Ensures the conjoint function that is formulated with conversion process.

The proposed framework includes different interviews to facilitate and is synthesized with various semi-structured interviews to describe the entrepreneur's success and failure in the sustainable energy sector. The existing system provides the action, loss, and success events to relate with the entrepreneur how research is focused mainly on the organization's background, specific entrepreneurship, and activities to narrate the sustainable energy sector's success and failure.

4. Results and Discussion

For entrepreneurs in the private sector to achieve success, the business Entrepreneurs are started; success is not always assured. Business must still go in an unpredictable direction. Thus, success or failure in entrepreneurship primarily depends on the entrepreneur's strength and weakness. It selected performance variables, accuracy, success rate, success rate, market outcome, the connectivity of research appearances in Notice whether, for XY, any increase (decrease) in (Rs+1 = B) often increases (decrease) in XY (Rs-1= B). Part of the paper and their position and significance for the business entrepreneur's success/failure will be checked. One aspect of the study will be to assess selected metrics of small enterprises' success/performance. It suggests to what degree the subjective assessment of owners/entrepreneurs/managers complements

Figure 172.6. Informal variable assigned.
Source: Author.

Figure 172.7. Accuracy of business entrepreneurs.

Source: Author.

the objective, conventional, and financial performance metrics.

The purpose of the research is to assess the complementarily of these categories of measures since, since they are small businesses, they display some characteristics regarding the real statement: the accuracy, efficiency, success rate, failure rate, and market results of business entrepreneurs.

It is a description of systematic errors, a measure of statistical bias; a discrepancy between a result and a "true" value is caused by low accuracy. The two definitions are different from each other above, so it can be assumed that a given data collection is either true, or accurate, or both, or neither. A straightforward yet unreliable string of results from the faulty experiment will be the outcome. The removal of systemic errors increases accuracy and does not affect accuracy. It can manage operations more efficiently, benefiting and clients, by accurately forecasting business. Figure 172.7 shows that in identifying current and potentially successful projects, further understanding the entrepreneurial process, and direct public policies to increase start-ups' accuracy, a measure of entrepreneurial performance is essential. The index's average value changes over time as businesses either boost their efficiency.

The efforts made in the decision-making processes by warning, agile and competitive entrepreneurs, while trying, on the one hand, to be innovative and creative, and while battling, on either hand, to take the initiative and to be ahead of competitors. The achievement of the set and entrepreneurial objectives is an entrepreneurial success. Compared to low-tech industries, company innovation has a more significant influence on high-tech performance, and the link between sustainable energy venture and performance is the strongest in Europe. Figure 172.8 represented a measure of entrepreneurial performance is essential in identifying current and future practical projects, furthering

our understanding of the entrepreneurial process, and guiding public policies to improve start-ups' performance. The Performance value is high compare with TEE, DSDM, SED, RBV, SvRPM. The findings indicate it sustainable energy entrepreneurship has a positive effect on business success financial indicators. The whole performance influence, which appears to be modest over the first few years, increases over time, implying that sustainable energy entrepreneurship can indeed be a generally successful way of enhancing long-term companies' financial performance.

When fresh and useful ideas are differentiated, creativity allows entrepreneurs to determine them from buyers and penetrate unknown territories. Consequently, innovative skills for leaders and staff have become critical.

Every day, it means more than beginning new ventures to be a successful entrepreneur. It indicates the correct position towards an entity and the commitment and desire to succeed. A successful businessman always has a strong sense of trust and a reasonable understanding of his strengths and abilities. About 80% make it through their first year when it comes to running a company. As the years go by, the proportion continues to reduce steadily. Presently 70 per cent survive their second year, and currently, about 30 per cent remain in operation by the tenth year. Regarded Figure 172.9 as, a measure of firm success is essential in identifying current and future success, furthering our understanding of the entrepreneurial business process and guiding public policies to increase the success rate of start-ups. In success Rate, the entrepreneur has expanded the business network level to sell the products.

Table 172.1 shows the proposed framework that determines the success rate of the entrepreneur with the sustainable energy sector. The success rate is determined with credit rationing, on the supply and demand side, is a limitation on the supply side. It occurs

because of the lack of knowledge of the creditor's right and the lack of SMEs' popularity. The result obtained with the comparative analysis shows the success rate as 72.55%, 81.2%, 75.66%, 79.22%, 78.26% and 95.06% for TEE, DSDM, SED, RBV, SvRPM and EOoAF respectively. Similarly, the analysis provides a better solution as there is an increased success rate with entrepreneur as 95.06% with EOoAF method.

Approximately half of all firms have lasted for at least five years, while a third of firms last for ten years. Entrepreneurs who fail to sell short changes favouring competing operations, especially RandD. After all, they cannot bear to spend money on ads and PR because their enterprises are invisible to the world. These are a big mistake when the cash gets tight, some entrepreneurs make. It takes a lot of time, money and effort to start a company, and failing or even going bankrupt is the last thing any business owner would want to do with their business. When it comes to avoiding company loss, remember the following points: Oversee cash flow, avoid stepping into debt, Build a strong company strategy, Maintain good service from customers, and learn from rivals in the market. When a corporation loses, it becomes directly accountable to

someone who guarantees a loan. It means the company is insustainable energy and the corporation owes the debts if it has secured the debt and will still be personally liable. Figure 172.10 described facilitating, evaluating current and potential failures, furthering our understanding of the company entrepreneurial process, and guiding public policy to reduce start-ups' failure rate. A measure of firm Failure is essential.

By incorporating new technology, goods, and services, entrepreneurs fuel economic growth. Increased entrepreneurial rivalry challenges existing businesses to become more successful. In the short and long term, entrepreneurs create new employment opportunities. A particular customer category to which a company markets its goods and services. Those who are most likely to buy from are target clients. In the hope of having a larger slice of the market, avoid the temptation to be too general. Figure 172.11 explains that a measure of the business market is essential in determining current and future marketing results, encouraging our understanding of its entrepreneurial mechanism and guiding public policy to reduce the start-up market ratio. The ratio of market outcomes is 99 percentages.

Table 172.2 provides the EOoAF to determine the reduced failure rate of the entrepreneur in the sustainable energy sector. Different failure factors such as financial capital, the inappropriate structure of government and weak infrastructure and corruption are discussed in which lack of access the most important is considered. The result obtained with the comparative analysis shows the failure rate as 28.5%, 8.19%, 11.69%, 37.48%, 21.01% and 13.48% for TEE, DSDM, SED, RBV, SvRPM and EOoAF respectively. Similarly, the analysis provides a better solution as the failure rate is reduced with the entrepreneur as 95.06% with EOoAF method.

5. Conclusion

Whether cross-cutting or more social and cultural business sustainable energy sector are often intentionally built and managed by managing directors. The cross cutting edge must have understood the value of cooperative activities for their companies to gain a competitive advantage; interaction and cooperation are valued by network members trust are genuinely established. It was best encouraged by brokers within the network programs who recognized and addressed the creation of sustainable energy sector from both an economic and a social point of view. The network's support consisted of brokers capable of mixing and overlapping the "hard" business and "softer" social interests of participants. They are best served by an initial Entrepreneurial Optimization of the adversarial system. The research further suggests that managing directors' mechanisms and motives to participate in company partnership and cooperation are based on social and economic rationalities. The network seller facilitators harness these desires and attitudes in a medium and atmosphere to create legitimate engagement and exchange vital to groups' survival. These models should evolve along with a structure with the intention of at some crucial point will ultimately be needed to "formalize the informal". In other words, strong formalized and sustainable sustainable energy sector should initially be catalyzed through an Entrepreneurial optimization of the adversarial framework of internationalization processes for entrepreneurship. The simulation results show the Entrepreneurial Optimization of Adversarial Framework achieves 97% accuracy, 98% performance, a 95% success rate, a 13% failure rate, and a 99% market outcome in representing the success and failure of the sustainable energy sector.

173 Evaluation of friction stir welds by ultrasonic inspection technique for Al 7075 and Al 7068

Rahul Mishra[a] and Gaurav Tamrakar[b]

Assistant Professor, Department of Mechanical, Kalinga University, Raipur, India

Abstract: The study explores the evaluation of friction stir welds in aluminum alloys 7075 and 7068 using ultrasonic inspection techniques. It provides a thorough examination of the use of ultrasonic phased array inspection technology, covering its guiding concepts, tools, methods, and specific outcomes. This research examines the unique difficulties, conclusions, and ramifications of assessing friction stir welds in certain aluminum alloys using ultrasonic inspection techniques. The goal of the analysis is to offer insightful information about the efficiency and future directions of ultrasonic inspection in assessing the caliber of friction stir welds in these particular aluminum alloys.

Keywords: Aluminum alloys 7075, 7068, friction stir welds, ultrasonic inspection

1. Introduction

The potential of friction stir welding, a novel solid-state joining technique, to produce exceptionally good welds in aluminum alloys 7075 and 7068 has drawn a lot of attention. Using a non-consumable rotating tool, this novel approach creates frictional heat that simultaneously softens and mechanically mixes the metals at the joint line. The end product is a high-strength, flawlessly formed weld with remarkable mechanical qualities [1]. This makes it the perfect technique for combining high-strength aluminum alloys that are frequently used in a variety of industries, including structural, automotive, marine, and aerospace. But maintaining the integrity and quality of the friction stir welds is still a vital step in the process, one that calls for advanced non-destructive testing techniques to assess these vital joints in great detail. The Difficulties and Requirements for Quality Control: Friction stir welding poses particular requirements for quality control, particularly in light of the high mechanical qualities and structural requirements of aluminum alloys 7075 and 7068. This section explores these issues and highlights the demand for sophisticated non-destructive testing techniques. Furthermore, these difficulties have prompted a critical investigation into ultrasonic phased array inspection technology as a reliable remedy for the complex quality control requirements related to

friction stir welds. Enhancing Non-Destructive Evaluation Techniques: Non-destructive testing techniques have evolved to meet the needs of sophisticated production processes. Because friction stir welding is so complex, a detailed, non-invasive way of inspecting and assessing the weld quality is required.

Ultrasonic inspection techniques, especially ultrasonic phased array technology, have demonstrated great promise as an enhanced mechanism for evaluating the weld quality of aluminum alloys 7075 and 7068 in response to these increasing demands [2]. A Brief Overview of Ultrasonic Phased Array Inspection Technology: This project investigates the basic ideas, setups, and tools used in ultrasonic phased array inspection technology. The emphasis is on describing the phased array probes' versatility, electronic scanning powers, and capacity to produce ultrasonic waves through constructive and destructive interference patterns. These specifics provide a solid foundation for using this technology to assess the mechanical integrity and quality of friction stir welds in aluminum alloys 7075 and 7068. Perspectives on Tools and Scanning Setups: The essential elements of ultrasonic phased array inspection technology are scanning configurations and equipment [19]. The Difficulties and Requirements for Quality Control: Friction stir welding poses particular requirements for quality control, particularly in light of the high mechanical qualities

and structural requirements of aluminum alloys 7075 and 7068. This section explores these issues and highlights the demand for sophisticated non-destructive testing techniques [3]. Furthermore, these difficulties have prompted a critical investigation into ultrasonic phased array inspection technology as a reliable remedy for the complex quality control requirements related to friction stir welds. Enhancing Non-Destructive Evaluation Techniques: Non-destructive testing techniques have evolved to meet the needs of sophisticated production processes. Because friction stir welding is so complex, a detailed, non-invasive way of inspecting and assessing the weld quality is required. These results show great potential in improving the efficiency and accuracy of ultrasonic inspection techniques for industrial applications, and they are essential building blocks for maximizing the non-destructive evaluation of the weld quality [4].

Ultrasonic Inspection Techniques: Their Potential and Future Consequences This section examines the research findings' ramifications and provides a strategic roadmap for the advancement of ultrasonic inspection technology [18]. A forward-looking analysis of the ongoing developments in ultrasonic inspection techniques for aluminum alloy friction stir weld assessment is provided by placing special attention on the future developments, including the industry impact and technological advancements. Ultrasonic inspection's multifaceted and intricate character is a major motivator for investigating its potential applications across several industrial domains, underscoring the importance and consequences of this revolutionary technique [5].

1.1. Friction stir welding

Friction stir welding is a significant advancement in solid-state joining techniques, especially when used with high-strength aluminum alloys like 7075 and 7068. Because of these alloys' remarkable mechanical qualities, they are essential in a variety of industries, including structural engineering, automotive, marine, and aerospace. For this reason, the effectiveness of friction stir welding is particularly important. When working with high-strength aluminum alloys such as 7075 and 7068, the essential component of friction stir welding—generating frictional heat using a non-consumable rotating tool—becomes extremely important in mitigating the inherent limitations of traditional fusion welding procedures [6]. By successfully softening and plasticizing the alloys, this technique overcomes common problems such porosity, solidification flaws, and liquidation cracking 1 and ensures the formation of strong bonds without the disruptive effects sometimes associated with fusion welding in Figure 173.1. The

importance of friction stir welding is highlighted by the attention paid to its improved mechanical qualities and microstructural benefits, especially when it comes to aluminum alloys 7075 and 7068 [7]. The production of flawless welds with remarkable mechanical qualities, such as increased corrosion resistance, high tensile strength, and improved fatigue performance—all essential characteristics for high-strength aluminum components in demanding applications—is made possible by this welding technology.

In view of the critical need for strong, lightweight, and long-lasting parts in sectors such as aerospace, automotive, marine, and structural engineering, friction stir welding of aluminum alloys 7075 and 7068 is basic [8]. Friction stir welding is a crucial enabler of advanced engineering solutions that meet strict performance requirements across a variety of industrial sectors because this inventive joining process makes sure that important factors like weld strength, structural integrity, and component longevity are effectively addressed.

1.2. Quality control challenges

This provides a perceptive examination of the complex quality control issues with friction stir welding, particularly as they relate to aluminum alloys 7075 and 7068 [9]. It emphasizes how important it is to have sophisticated non-destructive testing techniques in order to carefully assess the mechanical qualities and integrity of the final welds. The goal of this part is to give readers a better knowledge of the difficulties in guaranteeing the quality and integrity of friction stir welds, with a focus on the structural requirements and the high mechanical qualities of these aluminum alloys [10]. It emphasizes how crucial it is to assess these welds with previously unheard-of precision and efficacy, paving the way for a thorough investigation of ultrasonic phased array inspection technology as a reliable response to these complex quality control requirements.
Figure 173.1. Schematic of the friction stir welding process.

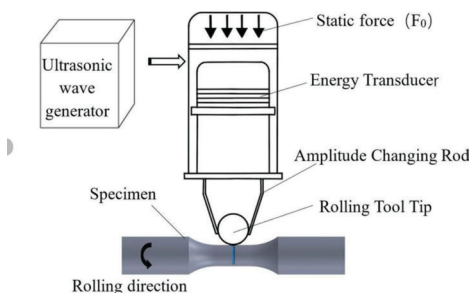
2. Ultrasonic Phased Array Inspection Technology in Aluminum Alloys 7075 and 7068

When it comes to evaluating vital components such as aluminum alloys 7075 and 7068, the fundamentals of ultrasonic phased array inspection technology are crucial. Because of their remarkable mechanical qualities, these high-strength aluminum alloys find extensive application in the aerospace, aviation, and automotive industries [11]. The efficient assessment of weld quality and mechanical integrity in these alloys requires an understanding of the basic concepts, configurational adaptability, and practical application of ultrasonic phased array inspection technology. This section describes the electronic scanning and beam-shaping capabilities of ultrasonic phased array probes, as well as how they produce ultrasonic waves through constructive and destructive interference patterns [12].

Additionally, it highlights how versatile this inspection method may be in evaluating friction stir welds in aluminum alloys 7075 and 7068, which are well-known for their crucial uses in structural parts that need to be very resilient to corrosion and strong. With a solid basis in these fundamental concepts, this technology serves as a cornerstone for accurate and effective assessments of mechanical soundness and weld quality in these crucial aluminum alloys, ultimately enhancing the dependability and safety of components in a range of industrial applications [13].

2.1. Equipment and scanning configurations

A thorough understanding of the tools and scanning settings used in ultrasonic phased array inspection technology is essential when working with aluminum alloys 7075 and 7068. These aluminum alloys are widely employed in the aerospace and defense industries for applications requiring outstanding structural performance because of their well-known high strength-to-weight ratio. The specialized tools needed for ultrasonic phased array inspection—such as sophisticated signal processors, specialist scanners, and phased array probes—are carefully examined in this section. The portion highlights the technological sophistication required for accurate evaluations by highlighting the adaptability and precision of this equipment, especially in the context of assessing weld quality and structural integrity in aluminum alloys 7075 and 7068 [14]. It also explores the particular scanning configurations used, emphasizing their versatility, accuracy, and significant consequences for reliable quality evaluation. The accuracy and versatility of these tools and scanning configurations are especially important for guaranteeing the integrity of friction stir welds in these high-strength aluminum alloys, which in turn improves the dependability and security of vital parts used in the automotive, aerospace, and aviation sectors.


3. Case Studies and Results

3.1. Conventional defect detection

The foundation for comprehending the efficacy of ultrasonic phased array inspection technology in assessing friction stir welds in aluminum alloys 7075 and 7068 is laid out in this section. It painstakingly examines in-depth case studies about the identification of common weaknesses such wormholes, voids, lack of penetration, and flaying surface defects [15]. This section offers valuable insights into the stringent quality control procedures and highlights the exceptional capabilities of ultrasonic inspection methods in the thorough assessment of the weld integrity and quality of these important and intricate joints.

3.2. Ultrasonic velocity and frequency measurements

The thorough examination of ultrasonic velocity and frequency readings gleaned from the examination of

Figure 173.2. Schematic diagram of ultrasonic surface rolling.
Source: Author.

Figure 173.3. Friction stir welding (FSW) tool and system setup.

Source: Author.

friction stir welds in aluminum alloys 7075 and 7068 is largely dependent on this section in Figure 173.2. By using accurate ultrasonic assessment techniques, the insights provided are crucial in assessing the integrity and quality of the welds [16]. Because of its effectiveness and precision in analyzing friction stir welds, this theme inquiry presents ultrasonic phased array inspection technology as a reliable and sophisticated mechanism for evaluating weld quality that has great promise in Figure 173.3.

3.3. Noise distribution and analysis

The examination of noise distribution measures highlights their significance in the evaluation of weld quality and adds another level of thorough study. This section provides nuanced assessments of the weld quality in various aluminum alloys by presenting a thorough examination and highlighting noteworthy developments in guaranteeing the mechanical integrity and quality of friction stir welds [17].

4. Discussion

4.1. Advancements in ultrasonic inspection techniques

Future improvements in ultrasonic inspection methods for friction stir weld evaluation in aluminum alloys 7075 and 7068 are discussed in detail. This section offers an outlook on how ultrasonic phased array inspection techniques could transform quality evaluation procedures in the industry by examining the current developments and future technical improvements in this field. The emphasis is on how advancements in ultrasonic inspection techniques in the future will improve essential weld evaluation's accuracy, effectiveness, and dependability. This will influence the future course of non-destructive testing for high-strength aluminum applications.

4.2. Industry impact and technological advancements

The possible ramifications and industry impact of the research findings on ultrasonic inspection techniques are highlighted in this section. The paper highlights how improvements in ultrasonic inspection techniques can spur innovation, raise quality control standards, and improve the overall dependability of welded components in industries that use aluminum alloys 7075 and 7068 by extrapolating the research implications to practical situations. The conversation also discusses the possible technical developments that could result from these study findings, providing an overview of

how non-destructive testing techniques are changing for use in industrial settings.

5. Conclusion

To sum up, this study investigated the use of ultrasonic inspection methods to friction stir weld evaluation in aluminum alloys 7075 and 7068 in great detail. The research examined the basic ideas behind ultrasonic phased array inspection technology, emphasizing its flexibility, scanning configurations, and capacity to produce ultrasonic waves for accurate evaluation. Through examining the difficulties and requirements for quality control associated with friction stir welding in high-strength aluminum alloys, the study emphasized the value of sophisticated non-destructive testing procedures, especially ultrasonic inspection methods. The results and case studies showed how successful ultrasonic inspection is at identifying traditional defects and carrying out precise velocity, frequency, and noise distribution measurements. These realizations are essential for streamlining quality assurance procedures and improving the assessment of mechanical integrity and weld quality in aluminum alloys 7075 and 7068.

174 Numerical and non-destructive analysis of an aluminum-CFRP hybrid 3D structure

Vinay Chandra Jha[1,a] and Shailesh Singh Thakur[2,b]

[1]Professor, Department of Mechanical, Kalinga University, Raipur, India
[2]Assistant Professor, Department of Mechanical, Kalinga University, Raipur, India

Abstract: In an effort to improve knowledge and guarantee the integrity of such composite structures in engineering applications, this work explores the numerical and non-destructive analysis of a hybrid 3D structure made of plastic and aluminium. The main goals of the study are to evaluate the hybrid 3D structure's structural integrity and performance using non-destructive testing methods and numerical simulations. The design, analysis, and assessment of the hybrid structure are all included in the study's scope, with an emphasis on experimental validation and numerical modelling. The literature study emphasises the growing significance of carbon fibre reinforced polymer applications and the value of aluminium structures in engineering. Furthermore, a number of non-destructive testing methods are covered in relation to evaluating composite constructions, such as thermography, X-ray imaging, and ultrasonic testing. The hybrid 3D structure's structural design, which combines CFRP and aluminium components, is described in the methods section. A thorough description of non-destructive testing methods is provided, together with an experimental configuration for thermography, X-ray imaging, and ultrasonic testing. The findings of the numerical study shed light on the hybrid 3D structure's structural response, including deformation properties and the distributions of stress and strain. The understanding of non-destructive testing results is made easier by comparing numerical and experimental data in the discussion section. The study's findings are finally summarised in the conclusion, which also recognises contributions made to the area and recommends future research directions, such as the progress of non-destructive testing techniques and the optimisation of hybrid constructions.

Keywords: Composite frameworks, analysis without destruction, CFRP utilisation, sound construction, computational models, modelling using finite element, sonography examination

1. Introduction

The search for materials with high strength-to-weight ratios in modern engineering methods has resulted in an increase in the use of hybrid structures made of carbon fibre reinforced polymers and aluminium [24]. In order to preserve the integrity of the structure and further our understanding of composite structure applications, this study explores the computational and non-destructive analysis of an aluminum-CFRP hybrid 3D structure [1-5]. The investigation of hybrid constructions is motivated by the growing need in a number of industries for materials that are both durable and lightweight [25]. Hybrid 3D constructions, which combine the special qualities of CFRP and aluminium, like strength, rigidity, and resistance to corrosion, have become attractive options for a variety of technical problems [8]. This study's main goals are to evaluate the aluminum-CFRP hybrid 3D structure's structural performance and integrity. The objective is to obtain an understanding of the behaviour of the hybrid construction under various loading situations by means of an extensive examination that includes both non-destructive testing methods and numerical simulations [6]. The project intends to improve design and analysis approaches for composite structures by gaining a deeper understanding of their response mechanisms [9]. The design, analysis, and assessment of the aluminum-CFRP hybrid 3D structure are all included in this work [7]. By means of this project, the aim is to establish a connection between theoretical understanding

[a]ku.vinaychandrajha@kalingauniversity.ac.in; [b]ku.shaileshsinghthakur@kalingauniversity.ac.in

and real-world implementations, thereby promoting progress in the domain of composite structures. The results of this investigation are intended to open doors for improved structural performance and optimised design approaches in engineering applications by tackling the difficulties posed by hybrid constructions.

2. Related Work

A number of recent research have made significant contributions to the continuing efforts in the field of composite structures by shedding light on the behaviour and functionality of hybrid constructions, notably those made of carbon fibre and aluminium reinforced polymers. The current research project, which is centred on the numerical and non-destructive analysis of an aluminum-CFRP hybrid 3D structure, is built upon these earlier works [14]. Research has looked into new alloy compositions and fabrication methods to improve the performance and structural integrity of aluminium components for a variety of uses, from the automotive to the aerospace sectors [15]. In addition, the increasing importance of carbon fibre reinforced polymers in engineering has led to an abundance of research endeavours focused on refining their mechanical characteristics and production methods [17]. In order to get the required strength-to-weight ratios and stiffness characteristics, recent developments in CFRP applications have concentrated on customising fibre orientations, resin formulas, and curing procedures [16]. The advantages of integrating CFRP with aluminium have been shown in earlier research on hybrid constructions. Concurrently, there has been substantial progress in the study of non-destructive testing methods, providing novel approaches to evaluate the structural integrity of composite materials [19]. The reliability of structural evaluation has been improved by recent advancements in the accurate detection and characterisation of interior flaws, delaminations, and material anomalies made possible by advances in thermography, X-ray imaging, and ultrasonic testing [18]. Using a combination of non-destructive testing methods and numerical simulations, this work attempts to add to the body of knowledge on hybrid 3D buildings, building on the insights obtained from these ongoing research endeavours [20]. The project aims to solve important issues and open up fresh possibilities for enhancing the performance and dependability of composite structures in engineering applications by using the developments in materials science, manufacturing processes, and inspection technologies.

3. Literature Review

Aluminium structures have been essential parts of engineering applications for a long time because of its exceptional strength-to-weight ratio, resistance to corrosion, and adaptability. Aluminium alloys are preferred in the maritime, automotive, and aerospace industries due to their lightweight nature, which improves performance and fuel economy. The spectrum of uses for aluminium structures has been further increased by recent developments in aluminium fabrication techniques, such as extrusion, casting, and additive manufacturing. Because of its exceptional specific strength and customised mechanical characteristics, CFRP is used extensively in the sports goods, infrastructure, automotive, and aerospace industries [22]. The synergistic benefits of combining CFRP with aluminium materials to obtain higher mechanical properties and performance characteristics have been investigated in previous studies on hybrid constructions. By fusing the great strength and formability of aluminium with the lightweight properties of CFRP, hybrid constructions take advantage of the advantages of both materials. The main goals of research have been to optimise hybrid structure design, fabrication, and structural analysis in order to reduce weight as much as possible, increase structural effectiveness, and improve durability under a range of loading scenarios [21]. Non-destructive testing methods are essential for assessing the dependability and integrity of composite structures, such as hybrids made of aluminium and C-FRP. The goal of this study is to fill in knowledge gaps regarding the numerical and non-destructive analysis of aluminum-CFRP hybrid 3D structures by synthesising the results of the literature review. The project aims to enhance design approaches, structural optimisation techniques, and inspection tactics for hybrid composite structures in engineering applications by means of thorough investigation and analysis.

4. Methodology

Several essential elements make up the technique for the "Numerical and Non-Destructive Analysis of an Aluminum-CFRP Hybrid 3D Structure" project. First, to confirm the structural integrity and functionality of the hybrid 3D construction, non-destructive testing methods including thermography, X-ray imaging, and ultrasonic testing (UT) are used to find material abnormalities and internal faults. By combining the findings of the literature research and improving design strategies, structural optimisation methods, and inspection strategies for hybrid composite structures, the study also seeks to close knowledge gaps [23]. Thirdly, the primary numerical analysis method used is finite element modelling (FEM), which simulates the mechanical behaviour of the hybrid structure under various loading situations using software programmes like ANSYS or Abaqus. Ultimately, in order to verify the results of numerical analyses and guarantee structural integrity, physical prototypes of the aluminum-CFRP hybrid 3D

structure are created utilising modern manufacturing processes, such as additive manufacturing or composite layup techniques. These prototypes also go through non-destructive testing. By gathering and examining experimental data, it is possible to assess how well numerical predictions match real behaviour, which guarantees the accuracy and consistency of the analysis methods.

4.1. *Design of the Hybrid 3D structure's structure*

Thermography, X-ray imaging, and ultrasonic testing (UT) are often employed techniques for identifying material anomalies, delaminations, and internal flaws without endangering the structure. By offering insightful information about the structural health and functionality of hybrid 3D systems, these methodologies enable prompt maintenance and repair actions to avert catastrophic failures.

The goal of this study is to fill in knowledge gaps regarding the numerical and non-destructive analysis of aluminum-CFRP hybrid 3D structures by synthesising the results of the literature review. The project aims to enhance design approaches, structural optimisation techniques, and inspection tactics for hybrid composite structures in engineering applications by means of thorough investigation and analysis.

4.2. *Methods of numerical analysis*

The main numerical analysis technique for simulating the mechanical behaviour and response of the hybrid
Figure 174.1. Functionally graded lattice structure analysis.

Figure 174.2. Density-variable lightweight structure analysis.

Source: Author.

structure under varied loading scenarios is finite element modelling, or FEM. To discretize the structure into finite elements and solve for stress, strain, and deformation distributions, finite element modelling software packages like ANSYS or Abaqus are used. The FEM models combine material parameters, boundary conditions, and stress scenarios to precisely forecast the structural performance and pinpoint important areas of concern.

4.3. *Procedures for non-destructive testing*

Non-destructive testing (NDT) methods are used to evaluate the hybrid structure's quality and internal integrity without causing harm. To find flaws, material abnormalities, and delaminations in the structure, thermography, X-ray imaging, and ultrasonic testing (UT) are used. When it comes to providing comprehensive internal photographs of the structure, X-ray imaging is used, while UT uses high-frequency sound waves to enter the material and find discontinuities. Thermography uses surface temperature changes to pinpoint possible damage or fault locations.

4.4. *Configuration for the experiment*

Physical prototypes of the aluminum-CFRP hybrid 3D structure are made in accordance with the designed requirements as part of the experimental setup in Figure 174.1. To create the prototypes precisely and consistently, advanced manufacturing techniques are used, such as composite layup procedures or additive manufacturing in Figure 174.2. The physical prototypes undergo non-destructive testing techniques such as thermography, UT, and X-ray imaging to confirm the structural integrity of the hybrid structure and validate the results of the numerical analysis in Figure 174.3. The collection and analysis of experimental data is done in order to evaluate the relationship between numerical forecasts and actual behaviour, guaranteeing the precision and dependability of the analysis techniques.

5. Numerical Analysis Overview

Several important topics are covered by the numerical analysis results for the project "Numerical and Non-Destructive Analysis of an Aluminum-CFRP Hybrid 3D Structure." First, the mechanical behaviour of the hybrid construction is examined under various loading scenarios using finite element modelling (FEM). By discretizing the structure into finite elements and using software programmes such as ANSYS or Abaqus, finite element modelling (FEM) makes it possible to forecast the distributions of stress, strain, and deformation. Second, the identification of crucial locations susceptible to material failure is facilitated by the complete insights provided by stress and strain analysis through numerical simulations into the internal forces and deformations encountered by the structure. This analysis plays a pivotal role in optimizing structural design and material choices to ensure sufficient strength and durability. Lastly, understanding the deformation characteristics of the hybrid structure is crucial for assessing its structural integrity and performance. Numerical analysis provides valuable information regarding deformation modes, magnitude, and behaviors, which assists in design adjustments and reinforcement solutions for enhancing structural stability and optimizing performance. Through these numerical analyses, the project aims to gain a deeper understanding of the hybrid structure's behavior and performance under various operating conditions, facilitating informed design decisions and ensuring structural reliability.

5.1. Modelling finite elements

To study the mechanical behaviour of the aluminum-CFRP hybrid 3D structure under various loading situations, finite element modelling (FEM) is a useful method. To discretize the structure into finite elements and solve for stress, strain, and deformation distributions, finite element modelling software packages such as ANSYS or Abaqus are used. To precisely forecast the structural performance and pinpoint important areas of concern, the FEM models incorporate material properties, boundary conditions, and stress scenarios. The reaction of the hybrid structure to external loads, including tension, compression, bending, and torsion, may be examined using FEM models, offering important insights into how the structure would behave in various operating scenarios.

5.2. Analysis of stress and strain

Numerical simulation-based stress and strain analysis provides comprehensive information about the distribution and magnitude of internal forces and deformations that the hybrid structure experiences in Table 174.1. High stress concentrations or excessive deformation are examples of crucial areas prone to material failure that can be discovered and addressed by analysing stress and strain distributions. In order to guarantee the hybrid 3D structure has sufficient strength, stiffness, and durability under operating loads, the analysis also makes it easier to optimise structural design and material choices.

5.3. Features of deformation

Evaluating the structural integrity and performance of the Aluminum-CFRP Hybrid 3D Structure requires an understanding of its deformation characteristics. Numerical analysis yields useful information regarding the mode and magnitude of deformation, as well as buckling, mode forms, and linear and nonlinear behaviours. It is possible to minimise excessive deformation and enhance structural stability by implementing design adjustments and reinforcement solutions through the analysis of deformation characteristics. Furthermore, the process of design optimisation for improved performance and dependability is aided by the identification of deformation patterns, which make it possible to forecast how a structure will respond to dynamic loads and environmental influences.

6. Non-Destructive Testing Overview

Three crucial methods are included in the non-destructive testing results for the project "Numerical and Non-Destructive Analysis of an Aluminum-CFRP Hybrid 3D Structure": thermography, X-ray imaging, and ultrasonic testing. Ultrasonic testing uses reflections of high-frequency sound waves to evaluate interior integrity without causing harm. While thermography uses fluctuations in surface temperature to identify anomalies, X-ray imaging offers detailed interior images to reveal concealed faults. These techniques provide insightful information on the state of the structure, making it easier to schedule maintenance and repairs on time to maintain structural performance and dependability. Combining these methods improves comprehension and helps with operating and maintenance decision-making.

6.1. Testing with ultrasonics

To assess the aluminum-CFRP hybrid 3D structure's interior integrity without causing damage, ultrasonic testing, or UT, is used. To find defects, delaminations, and inconsistent material, high-frequency sound waves are sent through the substance and the reflections are examined. UT offers insightful information about the internal state of the structure, making it possible to spot possible flaws and trouble spots.

6.2. X-ray imaging

To acquire fine-grained internal images of the hybrid construction and uncover any concealed defects, voids,

Table 174.1. Non-destructive testing

Technique	Capabilities	Limitations
Visual Inspection	Macroscopic surface flaws	Small flaws are difficult to detect, no subsurface flaws.
Microscopy	Small surface flaws	Not applicable to larger structure; no subsurface flaws.
Radiography	Subsurface flaws	Smallest defect detectable is 2% of the thickness; radiation protection. No subsurface flaws not for porous materials.
Dye penetrate	Surface flaws	No subsurface flaws not for porous materials.
Ultrasonic	Subsurface flaws	Material must be good conductor of sound.
Magnetic Particle	Surface/near surface and layer flaws	Limited subsurface capability, only for ferromagnetic materials.
Eddy current	Surface and near surface flaws	Difficult to interpret in some applications, only for metals.
Acoustic emission	Can analyze entire structure	Difficult to interpret, expensive equipments.

Source: Author.

Source: Author.
Figure 174.5. AC and DC component analysis graph.

Source: Author.

or discontinuities, X-ray imaging is employed. X-ray imaging offers thorough visualisations of the internal structure by passing X-rays through the material and recording the transmitted radiation on a detector. This makes it possible to spot flaws that might not be apparent from the outside. This method provides useful data for evaluating the integrity and quality of the hybrid 3D structure in Figure 174.4.

6.3. Thermography

The Aluminum-CFRP Hybrid 3D Structure can be used to identify any damage or faults by using thermography to measure variations in surface temperature. Through the process of thermography, infrared radiation released by the structure's surface is captured, making it possible to identify anomalies including delaminations, voids, and material degradation. This non-contact technique makes it easier to evaluate the structural integrity and health by offering quick and thorough examination results in Figure 174.5.

The X-ray imaging, thermography, and ultrasonic testing findings from the non-destructive testing provide important information on the integrity and internal state of the aluminum-CFRP hybrid 3D structure. By identifying defects, flaws, and material irregularities, these

procedures provide timely maintenance and repair activities that guarantee structural performance and reliability. Combining these non-destructive testing techniques improves comprehension of the structure's state and facilitates decision-making about upkeep and operation.

7. Conclusion

In summary, this study marks a major advancement in the field of hybrid composite structures in engineering. Through the use of a methodically planned approach that integrates numerical simulations and non-destructive testing methods, this study provides an extensive evaluation of the structural soundness, internal state, and functionality of the aluminum-CFRP hybrid three-dimensional structure. This study offers important insights into the mechanical behaviour of the hybrid structure under a range of loading circumstances by using finite element modelling (FEM). The distributions of stress, strain, and deformation are clarified by this study, which helps to inform important choices about material selection and structural design that are intended to increase strength and durability. In addition, the examination of deformation characteristics provides crucial information for assessing the integrity and performance of the structure, enabling focused design

adjustments and the use of reinforcing techniques to enhance stability and maximise overall efficiency. In addition, the use of non-destructive testing techniques like thermography, X-ray imaging, and ultrasonic testing provides important information about the interior state of the structure. Through the identification of flaws, defects, and anomalies in the material, these discoveries guarantee the continuous performance of structures and ensure prompt maintenance and repair without compromising structural integrity. Overall, this study contributes to our understanding of hybrid composite structures and lays a solid foundation for future research projects that combine experimental validation, non-destructive testing, and numerical analysis to improve the performance and reliability of these structures in engineering applications.

175 Academic transition towards digital architecture in Papua New Guinea

Daniel Ame[1] and Aezeden Mohamed[2,a]

[1]Department of Architecture and Construction Management, PNG University of Technology, Papua New Guinea, Lae, Morobe
[2]Department of Mechanical Engineering, PNG University of Technology, Papua New Guinea, Lae, Morobe

Abstract: In the 1990s, the Papua New Guinea Architecture School was established when pedagogy in architecture was still common. At that time, students were able to showcase their artistic abilities directly on drawing boards. However, only a small number of Papua New Guinean native students were permitted to enroll in the course, and even fewer were able to complete it and become architects and builders. The country and the nation, which had just gained independence, were still in their early stages. The facilities and teaching methods were entirely different back then from what they are now. Students were free to express their artistic skills through freehand sketching and manual drafting, without being limited to the use of technology like the current generation that has grown up digitally. As a result, the architecture program back then was more hands-on. The study of architecture in Papua New Guinea has evolved from traditional to digital over time. As the world moved from the industrial to the information age, architecture education in Papua New Guinea also underwent digitization. This has increased the level of digital literacy among aspiring architects. Students now have access to architectural sketching software from their first year of study. To balance the ever-evolving technology with the outdated curriculum, a new syllabus was created that incorporated digital technology as a separate topic. This has given students more exposure to digital architecture, allowing them to use digital presentations with 3-dimensional models and animations to communicate their ideas more effectively.

Keywords: Conventional teaching, digital architecture, digital literacy, manual drafting, digitalized generation

1. Introduction

This article examines how architecture has changed during the Papua New Guinea Architecture School's existence. It is a comparison between architecture as it was, as it is now, and as it will be in the future. Even more, consider how technology affects the learning of both current and former alumni. In addition, this study attempts to pinpoint the modifications that should be made to the current infrastructure to meet the demands of digital learning and the instructional aids that facilitate the effective delivery of course material.

This study's primary goal is to analyze the impact of digital technology on architecture academia and to list its benefits and drawbacks. This can provide a clear picture of the most critical areas to focus on to prepare pupils for the workforce. Its goal is to pinpoint certain competency areas students need to know about to focus their efforts on those areas for their professional growth. As a result, at graduation, students will have grown as professionals and be employable.

Indicators that strengthening the role of technology in the postmodern life society is characterized by the occurrence of the increased frequency of computer usage along with a lot of software application that they are using, change on the society life style that are utilizing electronics device entirely, the individual boost with higher education background to master the skill of computer technology, as well as the number of institutions that operates based on e-commerce and virtual community. Architect has been affected by digital technology and experiencing the significant development of using digital technology, where this digital technology allows architects to make an innovative complicated architecture design against the desired final form, the structure system usage, the function of the building, the material that is used and the affected environment. Starting from that, a study in-depth

about this digital architecture technology should be done mainly related to the theory, philosophical concept, evolution, research, fabrication, challenge, work and architectural work practice [1-5].

2. Transitional Period

The province of Manus is known for its traditional architecture, which has undergone a shift over time. Traditional vernacular architecture originated in Papua New Guinea during the ancestral era, where cultural and environmental factors influenced architectural design. However, during the 19th-century colonization, a new colonial idea was introduced, resulting in the standardization of architecture. This led to the decline of indigenous vernacular architecture in Papua New Guinea, giving way to post-colonial and contemporary architecture [6–7].

Post-colonial architecture is a combination of colonial Western architectural influence and traditional building methods. The locals continued to use their old building techniques, but with modifications that incorporated Western concepts. For example, ancient vernacular buildings in Manus Province featured bow roof rafters, but the locals used straight rafters instead of bow rafters during the colonial era. This is because their colonial overlords used straight rafters in their bungalow dwellings. Such instances of the influence of colonial architecture in different regions of the country are quite common [7–10].

Throughout history, the events that occurred have influenced the development of Papua New Guinean architecture. The country experienced a colonial period, and right after that, it was affected by World War II, which caused a lot of suffering. During the post-war era, a new ideology emerged as people recognized the importance of education and began to break away from their traditional ways of life. This opened the door to more outside influence. In 1975, the country gained independence, but the impact of colonialism remained and was assimilated into the culture, architecture, political structure, traditional systems, and religion. However, society eventually welcomed Western cultural acceptance [7–9].

During the colonial era, indigenous people in Papua New Guinea moved from province to province to work on plantations. The demand for coconut oil in Europe led to the significant trading company Godeffroy of Hamburg trading for copra in the New Guinea Islands, which resulted in German colonization of the country's north. The Germans employed people from different provinces, and many indigenous people moved to the Manus region to work. This movement had an internal impact on a national movement within the country, and diverse cultures began interacting and influencing each other [8–10].

Both external and internal factors influenced the architecture of Papua New Guinea. The indigenous people's movement from one province to another resulted in sharing their culture and influenced other cultures they encountered. The country is culturally diverse, with distinct traditional cultures even among tribes living in the same area. As people started to travel, they also took their customs with them [11].

The arrival of explorers began the external impact on the country's architecture, followed by missionaries, colonial officials, and eventually masters. Historical events enabled people to migrate from one location to another, resulting in direct human interaction and the spread of influence [11].

2.1. *From industrial revolution to informational revolution*

During the Industrial Revolution, many historical inventions were made in industrial mechanics. This period saw replacing hand-made tools with machines and the development of steam engines, factories, and automated manufacturing systems (Table 175.1). The industrial period started in Great Britain and the United States between 1760 and 1840. The end of the twenty-first century marked a breakthrough in electronics development, which led to the invention of computers and the start of the information revolution [11–15].

The information revolution, also known as the age of electronic gadgets, computers, and internet networks, has made many systems in the world more accessible, secure, and capable as illustrated in Table 175.1. This has resulted in the new, digitally savvy generation frequently surrounded by computers from a young age. With the advent of digitalization, academic architectural education began to incorporate technology, using software for computers to create drawings in three dimensions and with motion. This was a departure from the usual manual approach of architectural education during the Industrial Revolution, which involved sketching by hand on drawing boards using drawing aids [15–17].

2.2. *Drawing board period*

Drawing boards were initially used in the 17th century but became more widespread during the 19th-century industrial revolution. In the 1900s, drawing boards were a central feature of Papua New Guinea's architectural school, where students used various drawing tools, including drafting pens, lettering stencils, and flexible curves, to create their designs. During this

Table 175.1. Shows the timing for PNG's architectural transformation

Year	Historical Events	Architecture Styles	Architectural Academic Transition
1884	1. Colonial Period (Two different colonies)	Traditional Vernacular Architecture For instance, a row of Manus traditional homes in Patussi with bow rafters supported by piling above the river (picture Buhler)	Conventional information is acquired using conventional techniques. At the local level, practical teaching methods are employed. Elders impart information by using it in real-world situations, as learning comes from seeing with experience.
1904	2. Post-Colonial Period (Under one colony)		
1941	3. World War II		
1950–70	4. Post-War	Post-Colonial Vernacular Architecture A home in the Pere village, South Coast of Manus, once known as Patussi. The rafters of this home are straight, a hybrid design.	In PNG's architecture school, the traditional teaching approach is applied.
1975–90	5. Independence		
1990–00	6. Post-Independence	Modern Architecture PNG Parliament House. The building shape notably captures the multi-traditional vernacular architecture of many areas in PNG. It integrates all cultures in only one unique building form. (Photo by: PNG travel) Architect: Cecil Hogan.	In PNG's architecture school, the traditional teaching approach is applied. (Blackboard period): tudents drew and drafted on drawing boards.
2000–19	7. New Millennium	Post - Modern Architecture The House of APEC. Although the structure lacks a conventional shape, the design uses an abstract representation of a classic sail. Image: www.habusliving.comArchitect: Jim Fitzpatrick and *Conrad Gargett*.	In PNG's architecture school, the traditional teaching approach is applied. (Time of the whiteboard) - Students drew and drafted on drawing boards. - Software for computers was introduced.
2019–22	8. New Millennium (Covid 19 period)	Digital Contemporary Architecture Airport Momote Stingray, Manus Province. An abstract of a stingray, which is frequently found in Manus seas, is used in this structure. Architect: Allen Guo Investments Ltd The worship center of Baha'is. The design of this structure is an abstraction of a woven basket, which is widely distributed across the nation. It also represents unity. Despite being a religious structure, the dome is also in traditional PNG vernacular. The classic Manus Haus boi, or man's dwelling, is shaped like a dome. The architecture of Sepik contains facades as well.	Using digital technology in the classroom is known as "Digital Architecture" in PNG. (Online instruction technique) Owing to COVID-19, online instruction was implemented. - A brand-new three-year bachelor's degree in architecture was introduced. - Drawings created on computers. - Design using 3D modulation and animation.

Source: Author.

time, drawings were created by hand using a manual process, and students acquired drawing skills throughout their six-year bachelor of architecture degree—the six-year course aimed to prepare students for graduation and the workplace. However, in 2020, the course was divided into a two-year master's program and a three-year bachelor's degree [17–20].

In the past, drawing boards were placed on long benches across the studio, and students used tee or set squares, masking tape, and sheets to create their sketches. Students had artistic freedom and embraced Western architecture and indigenous arts. Drawing skills were combined with architectural drafting and documentation knowledge, establishing the importance of arts in architecture [18–20].

Traditional teaching methods were used in the past, where instructors provided students with notes to study and prepare for exams. However, modern lecturers use flipped learning strategies, where students are involved in research and create custom study materials relevant to the course material. This approach has become more prevalent in this generation, and online teaching has improved the delivery of course material [20, 21].

2.3. *Digitalized generation*

As Papua New Guinea moves towards digitalization, there are abundant opportunities for those who act. Deloitte Connecting PNG's publication predicts that the nation will eventually enter the competitive field of digital technology. In this regard, the Papua New Guinea Architecture School has successfully digitized its curriculum, which has helped the nation's architectural and construction sector to transition to digital technology, thereby increasing industry competition. Digital representation of architecture has become a powerful and marketable tool for architects who are entrepreneurs in the country. Graduate architects with solid digital architecture abilities are highly valued and referred to active architectural companies. The architecture school has included a digital architecture course in the first-year curriculum to emphasize the significance of digital technology in architecture and its professionalism in practice. Lecturers and academic instructors also use digital technology to educate students in various architecture-related disciplines. These days, design studios are digitally focused, and instruction is conducted virtually. Students are even assessed online through digitally systematized programs. Almost all universities and architecture schools in the country have digitalized their systems and procedures. For instance, to enrol in classes, students have to register online. The PNG University of Technology has digitalized several systems to enhance efficiency and effectiveness. The following text describes the digitalization of various services PNG University of Technology offers [21, 22].

The University has implemented an online student registration process to reduce lengthy lines during registration. A digital assessment system has been introduced to make it easier for instructors to complete assessments and declare students' academic statuses. Students are advised to turn in their assignments online via Moodle and Google Classroom, which helps maintain records and monitor student evaluations. Lecturers mostly use digital education methods, such as Google Meet, Zoom, PowerPoint, and video presentations, which allows them to instruct more efficiently [21, 22].

The University has also digitalized the staff payroll and file management systems, making storing and accessing staff data and records easier. Furthermore, the ICT department has digitalized the maintenance request system, allowing users to submit a maintenance request from the comfort of their office [22, 23].

Due to the limitations imposed by COVID-19 in 2019, the University started offering online courses in 2021, including community development studies, surveying, and business admissions. Finally, the University Library's catalogue has also been digitalized, making it easier for students to search for books [23, 24].

3. Impacts of Digital Technology on Architecture

3.1. *Negative impacts*

During the Industrial Revolution, architects relied heavily on manual drafting techniques. Many architects were skilled in both freehand sketching and manual drafting. However, the introduction of computer-aided software has revolutionized the field of architecture. As a result, architects must now possess basic IT knowledge to effectively use computer architectural software and programs. With the help of a mouse and keyboard, architects can complete most of their work digitally, leaving their hands free to perform other tasks [2, 10, 15].

Drawing and creative talent are essential for architectural design. These skills can either be innate or developed over time. To truly understand the artistic quality of architecture, one must have a deep appreciation for the field. Without this appreciation, structures can end up looking dull, monochromatic, and meaningless [5, 25]. On the other hand, a well-designed structure should be vibrant, aesthetically pleasing, and have exceptional multidimensional complexity. Achieving this requires a deep understanding of the digital applications used in architecture as well as the artistic talent of the architect [10, 13].

While art in architecture demands the artist's talent, digital architecture requires software literacy. An artistic architect draws with their hand, while a digital architect draws with their thoughts. An artistic architect uses their hands to bring their ideas to life, while a digital architect employs their thoughts to create designs using software. This is the main difference between digital architectural technology and hand-drawing. Therefore, when using computer software as a design tool, one may be limited in certain design aspects. As W. J. T. Mitchell once said: "Although it's evident that computers have had a significant impact on some aspects of architectural design and construction, these differences may not always be the emancipatory, progressive ones that are frequently depicted."

3.2. Positive impacts

The use of digital technology in architecture has brought significant benefits to building project design and construction. Time, quality, and money are three key components that are considered in the design and construction of any building project. Every project manager aims to complete the work before the deadline, within the allocated budget, and with high-quality standards. Digital technology has effectively addressed these three aspects, resulting in decreased labor costs, faster production times, and the same level of quality [17, 25].

The building industry has leveraged computer-aided drawings (CAD) and computer-aided machines (CAM) to incorporate technology. CAM is used to produce final goods for ordinary building needs, while CAD is often used in the design process. To cut and create building components using CAD plans, machines (CAM) were built to be compatible with CAD software. This has greatly facilitated and expedited the construction process [17, 24, 25].

4. Methodology

This study's methodology was based on a literature review, a questionnaire survey, and an on-site inspection of the Department of Architecture and Construction Management's teaching and learning spaces.

4.1. Survey

A survey was carried out on some academic staff of the Architecture and the Construction Management streams respectively. They were given questionnaires to fill using Google Forms. The main idea behind this survey is to get academic staff's opinion on what they think about the influence of digital technology in architecture in Papua New Guinea. Since some of the staff used to teach back in the 90s, they were familiar with the conventional method of teaching. However, they also transited into the digital mode of teaching in the current. Hence, they can give a good background on the advantages and disadvantages of digital technology in architecture.

The participants responded and their ramification clearly indicates the importance of digital technology in architecture while at the same time addressing the need of students learning manual drawing as a fundamental aspect of architectural design [23].

There were only six questions in this survey. Four of these questions are set out in a tick box format and two questions requires the participant to give long answers.

These questions a set out in a range from those that strongly agree, agree, disagree and or strongly disagree with the opinion stated in the question. The participant is required to tick the appropriate box according to his own opinion. The following are the tick box questions with the results in graphical illustrations.

Question one: Do you believe that it is necessary to utilize digital technologies in the field of architecture?

Question two: Due to the rise of digital technology, are students less interested in studying manual architectural drawings?

Question three: Is teaching students freehand sketching and manual drafting necessary before exposing them to computer design software?
Figure 175.1. Answer to the first query.

Source: Author.
Figure 175.2. Answer to the second query.

Source: Author.
Figure 175.3. Answer to the third query.

Source: Author.

Question four: Should architectural schools combine manual drafting and free-hand drawing with digital technology?
Figure 175.4. Answer to the fourth query.

Source: Author.

4.2. *Open ended questions*

Please note that the participants are required to answer the following questions using either a single phrase or a lengthy paragraph in Figure 175.1.

Question five: What is the opinion of students on digital technology versus traditional methods of understanding hand-drawn images?

The following are quotes from various participants regarding the use of technology in learning architecture:

Participant 1: Recent findings suggest that students prefer digital technology over traditional hand drawings. However, to understand the drafting skills required for digital architecture, students should first learn the fundamentals of manual drawing in Figure 175.2. This will make it easier for them to transition into digital media.

Participant 2: In my experience, students struggle with sketching by hand in Figure 175.3. They rely heavily on digital technologies and need to improve their drawing skills.

Participant 3: Students often abandon manual drawings because they take longer to understand, whereas they can quickly learn how to operate drawing software in Figure 175.4.

Participant 4: Although computers often amaze students, it takes time to become proficient with digital technology. Therefore, learning certain fundamentals through manual methods is better before advancing to digital media.

Sixth question: What impact has digital technology had on architecture?

Participant 1: Since digital technology is a constant in our lives, we must adjust. The future of architecture lies with digital technologies. It also diminishes the significance of the essential abilities required in all fields of labor, though. The saying "A newborn must crawl before they can walk" is spoken. In conclusion, hand drawing is becoming less and less relevant due to digital technology.

Participant 2: technology benefits architecture by making time management more accessible for teachers and students. Students may now combine many design programs to produce more complicated designs because of advancements in computer design.

Participant 3: The industry is expanding digital technology; thus, students need to stay current. Students better understand a design's shape, function, and buildability when they view designs in three dimensions. Presenting designs to clients is another essential and influential use of digital technology.

Participant 4: Despite its advantages, digital technology should be included gradually, particularly for first-year architecture students. Comprehending figurative work, such as sketches and model building, is essential. Before exploring digital formats, first-year students should be familiar with these foundational concepts. If education is not, education will become too challenging.

5. Results

The information is presented in the form of graphs, which are shown in Figures 175.5 and 175.6.

The data has been analyzed and is now presented as a percentage as shown in Figure 175.6.
Figure 175.5. Analysis of the results.
Source: Author.

Figure 175.6. Percentage analysis of the results.

Source: Author.

The analysis in the graphs on Figures 175.5 and 175.6, illustrates that while digital technology in architecture is advancing, manual drafting is becoming to loosen taste. Hence, lecturers are believing that students should not completely do away with manual drafting but have it blended with the digital technology in architecture. Manual drafting score 0% while Blended method has 63%. Digital technology has 37% which indicates that digital technology in architecture is also recommended for today's architectural practice [20–27].

6. Location Evaluation

Building facility upgrade. The transition in digital technology also emphasized on better building facilities and services. Any digital installation to an existing facility will also attract the notion of facility upgrade in terms of electrical energy supply, back-up systems, new air condition installations, renovations and security systems. Some of the buildings were constructed when the use of power energy was very minimum, however when additional installation such as air conditions, internet systems, computers and security systems become demanding, an upgrade is definitely required [3, 22].

The building that housed the Department of Architecture and Construction Management was constructed back in the 90s when the use of electricity was not demanding. There were only ceiling fans, lights and few general power outlets (GPO) installed in the building. However, in this 21st century when digital technology in architecture was amalgamated into the architecture program, a lot of needs and requirements were realised. There was a need for a computer laboratory to be included with very fast, high graphic computers to cater for high standard resolution for 3D animation works. A need for air conditions to keep electronic equipments cool and the demand for more GPOs in the studios for students to use increased.

In the 90s students used drawing boards thus the need for electricity was not prioritized. However, the students of the 21st century all have laptops and most drawings were done using computer aided drawing softwares. Hardly one can see a drawing board in the architecture studios these days, then in the past when all the studios have drawing boards [23, 24].

With all the recommended requirements, specifications were done to support the need for facility upgrade. The following are some of the proposed upgrade required on the building facility in order to completely digitalize the department.

6.1. Digital laboratory extension

The Architecture School needs to upgrade its computer lab with new computers and software to facilitate digital learning. Students require access to a computer lab with powerful machines capable of handling complex graphics. It is recommended that the lab is upgraded and expanded to allow students to utilize 3D animation and modulation.

To ensure the digital laboratory remains operational during a blackout or power spike, it is essential to install an uninterruptible power supply (UPS). Additionally, to address the lack of electrical power outlets, more outlets should be added to each design studio and lecture hall.

To avoid power outages, installing a standby solar energy backup system is recommended. Air conditioning units must be installed in the digital laboratory to cool the computers and other electronic equipment.

To facilitate learning, stationary projectors should be installed in every lecture hall, and the facility should be renovated to meet international architecture school standards. Suitable chairs and tables must be provided for all staff members and students.

Upgrading the WIFI equipment and installing LAN connections in all studios and lecture halls will enable staff and students to access the internet and switch to using LAN connections when WIFI services are not working well. Decentralizing library services will enable students to research in the comfort of their department.

7. Expectation of the Industry

7.1. Industrial associations

The PNG Board of Architects is responsible for setting policies to regulate and uphold professionalism and standard practices in the construction sector. It receives reports from the PNG Institute of Architects, an association that ensures architects are registered. The board is a parliamentary legislation that ensures compliance with relevant regulations.

To become a working architect, graduating architecture students must register with the Institute of Architects and obtain authorization to practice. There are specific conditions an architect must meet to become registered, including extensive training, experience, and qualifications to uphold the necessary professionalism and standards.

Aspiring architects must understand these prerequisites to focus their efforts and advance their professional careers. The country's architectural schools' course syllabi also cover most of these prerequisites [25–27].

7.2. *Student architect competencies*

The school aims to prepare its students for the workforce by targeting the industry and adhering to the standards set by the Association of Architecture Schools of Australasia (AASA). The AASA has 72 different abilities that it requires from its graduates. However, the PNG industry has specific requirements, which include skills related to schematic design, design development, contract administration, contract documentation, tendering and negotiation, project management, research and feasibility study, communication, procurement and logistics, computer software proficiency, and free-hand sketching [28, 29].

According to the PNG Institute of Architects, architect registration requires competency in the first six abilities. However, students need to acquire additional competencies to succeed in the sector after graduation. This will enable them to function without difficulty [24–29].

8. Conclusion

Digital technology has become an integral part of our lives and is used to organize everything for security, accessibility, and efficiency. In order for architecture students and construction managers to understand digital technology in architecture and become proficient, they must participate in effective digital learning. In addition to manual architectural drawing, contract administration, project management, procurement, and other architecture competencies listed in the Association of Architecture Schools of Australasia (AASA) requirements, digital architecture must also be suggested as a competency requirement for graduate architects.

Although the survey findings provide strong evidence in favor of the digitalization of instruction, a mixed-learning approach is also necessary to help students understand the creative aspect of architecture. Drawing is an essential part of the design process, and concepts cannot only be thought of but must be sketched to be seen. Digital software is only used for the final output of the product and serves as a design tool for manufacturing and display. Therefore, to prepare students for business success, they should be taught both manual and computer-aided drawing in a blended learning environment.

176 PNG defence force officially introduced force 2030 doctrine as a pivotal component of its forthcoming strategic framework

Joshua Dorpar[1] and Aezeden Mohamed[2,a]

[1]Department of Business Study, Papua New Guinea University of Technology, Papua New Guinea University, Lae, Papua New Guinea
[2]Department of Mechanical Engineering, Papua New Guinea University of Technology, Papua New Guinea University, Lae, Papua New Guinea

Abstract: There have been no significant policy changes, organizational structure adjustments, or changes made to bring the Papua New Guinea Defence Force (PNGDF) in line with the objectives of the Government of Papua New Guinea (GoPNG) or the National Development Plan (NDP) since its establishment following independence in 1975. Since the Australians took over the organization as soon as Papua New Guinea gained independence in 1975, its foundation, systems, and structure have yet to be modified to fit the demands of the modern national, regional, and global security apparatus. The GoPNG has included the Medium-Term Development Plan (MTDP) policy change in its five periodic development plans to address this issue. This reform aims to restructure the PNGDF and increase its personnel to 10,000 by 2030, in line with the growing internal and international security trends. The Force 2030 Policy and Defence White Paper 2013 provides the policy guidelines and execution plan for this reform. To ensure that the Force 2030 policy is effectively and efficiently executed, implementation timetables have been phased out to maximize the decentralization of effort. However, the policy's implementation has faced internal and external obstacles, and the period of renown has elapsed. To achieve the GoPNG's goal of having 10,000 personnel by 2030, the Force 2030 document must be examined and evaluated to ensure that it aligns with the GoPNG's existing MTDP goals. Only then can finances and resources be available to execute the policy within the allotted period properly. To accomplish this aim, a review is required, and a new "bridging policy document" must be created to merge MTDP III 2019–2022 and MTDP IV 2023–2026 and realign Force 2030's business purpose and intent.

Keywords: Defence act, defence force, policy document, defence white paper 2013, force 2030 policy

1. Introduction

The Defence Act of 1974 and Chapter 74 of the PNG Constitution established the Papua New Guinea Defence Force (PNGDF). This organization has undergone leadership changes, from the Australia Defence Force to the PNG Defence Force, and has had thirteen commanders. The Australian Defence Force provided the PNGDF with existing doctrine on administration, operation, routine, discipline, organizational structure, and other necessary manuals before PNG's independence in 1975. These doctrinal procedures served as the cornerstone of the PNGDF until the Bougainville Crises, which tested the doctrine and processes. During the civil war with the Bougainville Revolutionary Army (BRA), the PNGDF's foundational structures, procedures, and methods were tested. The PNGDF's capacity to fight in the civil war reflected its personnel strength and capability, giving it an advantage over the BRA. However, the PNGDF became complacent after the crises, and the structures and procedures that maintained its fundamental unity weakened severely. As a result, there is a need for significant organizational or policy reforms to rebuild the PNGDF and

maintain its unity [1–3]. The first steps to reconstruct the force involve changing the regulatory and policy frameworks to account for the changes and comply with the suitable governance protocols. The necessary administrative and legal standards must strictly bind the procedures. All laws and policy amendments must align with the government's development policy plan, including the National Goals and Directive Principles (NGDPs) and the Medium-Term Development Plan III (2018–2022), which establish the objectives and goals for national building, including creating the framework for national security policy [1–3].

2. Policy Documents

One of the plan's components is national security, which aims to create a dynamic defense force that can respond to the nation's defense and security needs and address the urgent need for infrastructure development, emergency relief services, and natural disaster relief for the country [3, 4]. The PNGDF and the Department of Defence were created by Section 188 of the Constitution and the Defence Act of 1974. The PNGDF's functions are outlined in Section 202 of the constitution, while the DoD's functions are outlined in Sections 5 of the Defence Act and the Public Service Management Act of 1986. The GoPNG must lead the relevant policy framework, including enabling legislation and resources to execute the NSP successfully to address institutional policy gaps and frameworks. 8 of this paper serve as the basis for the reconstruction of the PNGDF, and this policy document lays that foundation. The Defense White Paper of 2013 included the Force 2030 Structure implementation strategy, enabling the policy framework to initiate an organizational reorganization to handle the rise in manpower to 10,000 by 2030. The Defence Act 2019 is the outcome of the regulation revision to the Defence Act 1974 implemented to implement this restructure. The establishment of the Office of the Deputy Chief of Defence Force and the promotion of interdepartmental heads to Branch Heads resulted from this amendment's implementation [6]. The future of the defense force lies in this policy framework, as the functional and strategic command will be upgraded to a Tri-Service organization to fulfill future force needs. Before implementing this policy, the Defence Act 2019 must undergo another assessment and change to account for organizational reorganization and personnel expansion.

3. Literature Review

As a result, the department needs to make the most of its resources to improve and profitably or practically

apply policy at the lowest possible level of commendation and sectors. This evaluation will examine how the Department of Health has carried out its policy as an output of the input created and approved by the Government of Papua New Guinea [6–8] to enhance the systems and services provided to the PNG public in their area of competence [7–10]. The GoPNG has created national health policies to further this agenda in an international attempt to decentralize the health system so that the duties and obligations of administering and offering the best medical care to the public are devolved to the lowest level [6–8]. The planning and execution activities of the District and Provincial Health Administrations are critical to the effective execution of the national health policies and programs [1,10]. Therefore, to enable the respective implementors at all levels of the government system to fully implement the policy as necessary to achieve the goals set forth by the GoPNG and the National Department of Health, this policy framework under the NHP will offer guidance and directions to all parties involved in the health sector throughout the nation [6–7]. Therefore, to fully use the advantages and achieve the desired outcomes that the NDoH and the National Government have anticipated, all of the NHP's fundamental principles must be adopted in every area of the health system. The NHP serves as a guide for health managers to ensure the health systems are managed in compliance with the standards established by the National Government. At several levels of the health systems related to the NHP, implementation issues provide obstacles in the implementation stages. This suggests a breakdown in how government and NdoH policies are being implemented, hindering the country's efforts to improve healthcare management. Identifying the Crucial Elements for NHP Planning and Execution The long-term goal of the NHP is to serve as the basis and direction for providing health services.

4. Methodology

To ensure the successful implementation of a policy, it is essential to examine the progress of its implementation. The Government of Papua New Guinea [6-8] has introduced the MTDP IV plan for 2023–2027, which includes the development policy for the Department of Defense. The policy is based on the assumption that the Force 2030 is currently in progress for complete implementation as per the set schedule. However, the policy's implementation has taken longer than expected, and thus, it is necessary to review, repurpose, and re-objectivize the policy implementation timetable to advance the process.

The Force 2030 policy aims to comply fully with the Defence Force Act 1974 (as revised in 2019) [1–6],

which permits organizational restructuring and the recruitment of 10,000 service members by 2030. In line with the 2013 Defence White Paper, the previous Chief of Defence Force, Major General Gilbert Toropo (rtd), announced that the Papua New Guinea Defence Force's workforce must increase to 10,000 by 2030. Therefore, it is crucial to align the policy's implementation with its desired objectives to achieve the set goal.

The policy's implementation has already achieved some objectives, while others are yet to be fulfilled within the given timeframe. To align with the GoPNG's MTDP development goals, all policy objectives must be achieved within the set timeline. For the successful execution of the policy, Force 2030 has set time limits, objectives, priorities, and expected outcomes to ensure that the policy's overall desired goals are achieved both internally (PNGDF) and internationally (GoPNG).

The policy and development plans in each government sector, including the Defense Organization, are interconnected and related to the GoPNG state agencies' overarching development strategy. The GoPNG and its affiliated government agencies determine the need for reform and the policy directives applicable to each sector and department. The MTDP III (GoPNG, 2018) outlines the yearly objectives for each indicator in detail, which are based on the Force 2030 strategy. The indicators must be met within the given timeline to achieve the GoPNG's aim in terms of national development and target regions. To develop policies that will benefit or develop the end-users (PNGDF), the operation strategy integrates the GoPNG's intent (input) by deriving policies (Force 2030/MTDPs) through responsible government agencies (Department of National Planning and Monitoring, Finance, Treasury, Defense, and others). This process will indicate the GoPNG's output and the indicator bar regarding development and policy implementation. To facilitate the decision-making process and competitiveness priorities, an operation framework matrix [12–18] is used to offer a perspective and framework of the operations strategy about the processes of policy inputs, initiation, and outputs. It emphasizes the methods of a predetermined strategy's decision-making and competitiveness goals [15–18].

4.1. Policy inputs

The GoPNG outlines the purpose and goal of the Defense Organization for a given period, as well as the outcomes it must achieve in its development plans. The policymakers may verify that the policy has undergone quality control and vetting using the performance targets shown in Figure 176.1. This is especially important for the policy's legal framework, which has to be both strict and adaptable for the policy to be implemented. Policy implementors' ability to carry out the policy within a specified timeframe and by national development objectives depends on their budgetary and scheduling constraints. The Chief of PNGDF has presented his strategic visions for 2022–2026 through the GoPNG development plan. This is a five-line plan of efforts that focuses on people (effectiveness of morality and discipline), organizational reforms (Force 2030), operational efficiency, infrastructure development, and nation-building capacity (MTDPs) [18–20]. As we move toward Force 2030, Defense 50, and the fulfillment of our portion of the GoPNGs Vision 2050, by completing these Lines of Efforts, we will establish a baseline for the future and a solid, resilient foundation for future growth and capability development across the entire force [3].

4.2. Initiators

To carry out the Force 2030 policy, the Defense Organization needs to be able to fully process the policy into implementation mode for the organization to grow. This includes technical expertise, subject matter expertise (SME), infrastructure, technological expertise, financial capacity, and inter-agency networking. This is the essential element of the policy's implementation operation plan, where vital choices are made for this matrix sector. The Defense Organization's ability to withhold resources and implement policies entirely within the time limit specified by the policymakers is the basis for decision-making.

4.3. Output

By reforming the PNGDF to realize the GoPNG's vision, the organization will accomplish the goal and aim of the GoPNG by applying the policy. The KPIs are indicators that will enable the GoPNG to assess and gauge the efficacy of the policy's implementation

Figure 176.1. Operations strategy matrix [18].

Source: Author.

and keep an eye out for any necessary improvements or modifications to better align with the organization's goals. As part of the ongoing implementation process, the Office of the Deputy Chief of Defence Force was established in 2021, marking the beginning of the policy's top-down implementation procedures.

4.4. PNGDF structure changes

By the Defense Act of 1974 (as revised in 2019), the organizational chart has already been reorganized as part of the Force 2030 strategy execution. The Force 2030 structure of the PNGDF and the existing structure are depicted in Figures 176.2–176.5 [4].

Explains that the current policy implementation (Force 2030) has inconsistencies and mismatches between its formulation and execution. The policy is compatible with the MTDP III 2017–2022. The

Baseline Manpower Restructure must reach 6000 people by 2022, as specified in Table 176.1 National Security and Defense Log frame. This strategy is also reflected in the Sustainable Development Goals (SDG) indicators.

Explains that the implementation method determines the success or failure of policies. The Force 2030 policy implementation strategy relies heavily

Source: Author.

on the top-down approach, assuming every procedure and stage is completed chronologically. However, this approach has resulted in overoptimizing factors such as complexity, evidence base, misunderstanding of stakeholders, and accountability. The disconnected relationship between the national and sub-national levels has also contributed to the policy's shortcomings. The political cycle in the development plans and strategies is also a significant contributing factor.

The policy aims to create a dynamic defense force that can respond quickly to the country's demands for security and defense and urgent infrastructure development, emergency relief, and disaster relief. Table 176.1 shows the log frame for military personnel's defense and national security baselines from 2017 to 2022.

The implementation of policies can be affected by disparities in policing and five-year government transitions, which can vary depending on different governments' priorities and points of view. To keep policies aligned with their intended goals, monitoring agencies must do an excellent job of following up and assessing them. In the case of the GoPNG, there are three essential areas where monitoring agencies need to improve their policy evaluation: performance monitoring, issue solutions, and progress evaluations. The implementation agency (PNGDF) needs an adequate budget, infrastructure, and human assistance to achieve the policy's KRAs and KPIs. Funding is the primary center of gravity (COG) for the PNGDF's execution of Force 2030. However, inconsistent financing and program offerings from GoPNG can slow the policy's implementation.

To ensure that the Force 2030 policy is implemented with the highest standard and quality, it must integrate Total Quality Management (TQM) with the policy implementation strategy. TQM is a management and process improvement method that can help with this objective. The policy is already in the transition phase and has been implemented at the agency level. To maintain its integrity, the methods and procedures for implementing the policy must be strengthened and reoriented to better fit with GoPNG's current goals and focus. The PNGDF leadership must involve every member to balance and lessen opposition throughout the implementation stages. The implementation process must be an all-encompassing (external) approach, and all expenses associated with the implementation process must have a singular goal: to optimize returns on investments via the mitigation of preventive costs integrated into the implementation's operational costs. Every step of the implementation process must be foreseen and prepared to prevent unnecessary delays. Adding an inspect-in (appraisal-driven) strategy to a design-in (doing it right the first time) approach can make it more cost-effective and time-efficient. To guarantee that the policy's goals and integrity are upheld

during the whole process, an impartial (outsourced) team must evaluate each of these procedures.

5. Results and Discussion

Determining Important Elements for Formulating and Implementing the Force 2030 Policy (Progress). Force 2030 Policy Schedule of Implementation: There has yet to be an implementation timeline for the Force 2030 Policy. This is because there is no implementing agency (PNGDF) or ongoing reviews to guide the implementation process. It is concerning that the policy has yet to be fully implemented within the time frame specified in the MTDPs leading up to 2030. The implementation processes have been derailed and have yet to produce the desired results by the deadline in each phase. A strategic approach must be implemented to ensure the policy is fully funded and supports the whole-of-government approach in the national development agenda. The strategy must be aligned with the national development plan and GoPNG's policies. Figures 176.6 and 176.7 show the strategy for implementing

Table 176.2. Activities, description, and time interval in years for Force 2030

Source: Author.

the policy moving forward, including the precedence graph and the Gantt chart for ET and LT, respectively. Table 176.2 illustrates how the implementation programs are divided into Activities (A–G).

Implementation Challenges: To implement the Force 2030 Policy within budget, according to the national development plans and goals of the GoPNG and the PNGDF[6–8], the following issues need to be resolved, enhanced, and mended: financial limitations (inadequate resources); poor training and education resulting in a lack of SMEs (subject matter expertise) to conduct organizational reform and reorganization; cultural disparities inside the organization between the old and new changes (opposition from both the inside and the outside); opposition from organizations, associations, and people; the inability of internal and external government entities to coordinate to execute the reform effectively; Lack of leadership; insufficient awareness and readiness on the part of the organization's internal and external stakeholders.

The term 'lean operations' refers to the process of delivering goods and services to customers at the lowest feasible cost, precisely when needed (not too early or too late), precisely where needed (not at the incorrect location), and precisely what they want (perfect quality). All actions listed in Table 176.1 must be carried out precisely according to the goals of each phase by coordinating the operation strategy and process flow in all areas of the execution of the policy, including internal and external processes. To secure ongoing financing for the implementation phase, the implementation must be coordinated and included in the NDP and other GoPNG development plans (MTDPs) [6-10]. The staff's behavioral engagement in ensuring that the processes are well-coordinated and synchronized in all phases of the implementation processes—at all levels of command—cannot be overstated to adhere to all the synchronization effects. Doing this meets the anticipated time frame for policy implementation and demand. The NDP is subject to periodic revisions in response to domestic and international demands. As such, the policy implementation of Force 2030 must be initiated and completed within the designated timeframe to achieve both the program's and the GoPNG's goals, which align with the MTDPs. There will be wastes and unintended or residual effects that impede the adoption of processes to achieve a quality policy. These lean processes will detect, remove, or eliminate these types of waste to prevent needless delays in time and resource allocation. The primary goal or emphasis is implementing the Force 2030 policy [15–20].

6. Conclusion

It has been found that the Force 2030 strategy, which aims to increase the number of members in the PNGDF to 10,000 by 2030, has yet to be implemented since it was first introduced in 2018. Although the Office of Deputy Chief of Defence Forces and the Branch Heads have been established, the fundamental restructuring of the policy still needs to be completed. Even though the PNGDF was supposed to have recruited and increased its manpower to 6,000 by 2022, this goal has not been achieved.

As a result, the GoPNG has introduced a new development plan, MTDP IV 2023-2026, with priorities and agendas regarding national security policy, of which the PNGDF is a part. However, a policy disconnect exists to execute MTDP III, which includes Force 2030 entirely. Funding and resources allocated thereon will follow MTDP IV and its outcomes, NOT MTD III or its outstanding output.

To integrate MTDP III and MTDP IV in terms of Force 2030 as part of a development policy in the PNGDF, a strategic approach and business process reengineering (BPR) is required. This will redesign the strategy and processes to achieve an integrated framework that will improve the effort and performance of policy implementation, including funding, resources, and time schedules.

To implement this policy, the following BPR components should be used:

1. Rethink business processes: Align the Force 2030 implementation to be incorporated into the MTDP IV 2023-2026 by creating a new policy document.
2. Aim for significant improvements: Redesign and realign the Force 2030 implementation processes, and create a new bridging policy document that unifies the policies and their timelines, agendas, and procedures.
3. Divide and decentralize roles: To fulfill the overall demand or phase's output, boosting production and maintaining flexibility in executing needed tasks will be possible by dividing and decentralizing roles within each phase and stage of the implementation processes.
4. Place decision-making points at the locations of the tasks: Group teams according to industries or areas of expertise and facilitate simple access to give yourself greater control throughout implementation.

In conclusion, a binding or bridging policy paper must be developed to realign the business processes and policy outcomes to suit the current NDP trend and goals of GoPNG. Force 2030 is one of the sub-policy papers at the National Security level of PNG's Medium-Term Development Objectives and Goals. This will be achieved through an integrated development agenda by all agencies and government departments (PNGDF).

[2]South Pacific Brewery Heineken, Morobe Province, Papua New Guinea

Abstract: The project focuses on studying high water usage in bottle washing machines, which is a crucial combination of environmental sustainability and industrial efficiency. Overusing water leads to increased utility costs, compliance issues, and severe threats to ecological integrity and operational sustainability. To tackle this issue, Root Cause Failure Analysis (RCFA) is employed to identify underlying reasons and provide solutions. The study specifically looks at the case of the Heineken SP Brewery, pinpointing the crucial water utilization areas in the bottle washer equipment and investigating the factors leading to excessive consumption. The study demonstrates that systematic analysis and countermeasure execution, such as setting cleaning standards, enhancing operator awareness, and implementing routine maintenance, lead to significant reductions in water usage. The results highlight the effectiveness of the RCFA approach in addressing water usage problems and its applicability across various sectors. This study underscores the importance of systematic problem-solving methods for achieving operational efficiency and environmental sustainability, thereby contributing to a broader understanding of water conservation measures in industrial settings. It's worth noting that most brewers, including Heineken, use the root cause failure analysis method to minimize waste and losses.

Keywords: Bottle washer, failure, machine, root cause, water

1. Introduction

Investigating the causes of high-water consumption in bottle-washing equipment is crucial for improving industrial efficiency and environmental sustainability. Excessive water usage is a major concern in this area that poses challenges for operations and the environment [1].

When it comes to bottle-washing equipment, the large amount of water used for cleaning and meeting regulations is a significant issue. This not only leads to higher operational costs but also results in increased utility bills due to rising water tariffs and charges. There is also a growing concern about complying with stricter environmental laws to reduce water waste [1, 2].

This investigation carried out alongside Root Cause Failure Analysis (RCFA), aims to address the challenge of high-water consumption in the bottle-washing equipment. Excessive water use not only increases costs but also raises concerns about meeting regulations and environmental impact. The root causes of this issue are diverse, including equipment inefficiencies, poor operational practices, inadequate maintenance, and reliance on outdated technologies.

To effectively address these challenges, a thorough examination using the RCFA method is necessary to uncover the underlying causes of excessive water usage and propose solutions to promote water efficiency and conservation in industrial settings [3, 4]. By understanding the relationship between operational practices, technology, and environmental impact, stakeholders can work together to reduce water wastage, improve operational efficiency, and ensure the long-term sustainability of industrial processes and ecosystems.

Given the rising costs and the need to protect the environment, it is important to understand why bottled washing machines use so much water. This research

aims to identify the causes of high-water consumption, using a case study of a beverage plant bottle washer equipment to understand these factors [5, 6].

2. SP Brewery

The bottle washer machine at the Heineken SP Brewery is designed with multiple treatment zones to ensure thorough bottle cleaning. The bottles are transported on a conveyor to an automatic infeed, where they pass through infeed channels and are pushed into the pockets of the bottle carriers by rotating segments. These bottle carriers, suspended on strong chains, then move through pre-soak, caustic soaks, and spray zones. Once cleaned, the bottles are released from the carriers at the discharge and transferred to a bottle conveyor using rotating segments. From there, they are fed to the downstream machines of the filling line. Figure 177.1 provides a visual representation of the eight stages of the bottle-washing process [7, 8].

2.1. The bottle washer uses water

Service water is supplied from utilities to the bottle washer and distributed to different compartments for use, as shown in Figure 177.1. Water is used in three main areas in the equipment: the rinsing compartment (pre-rinse stage), detergent compartment (caustic baths), and post-rinse compartment (post-rinse stage) [5–8].

Pressure sensors measure the levels in the compartments (see Figure 177.3a). Level control for different treatment zones is achieved using limit switches and Pt1000 RTD, as shown in Figure 177.2. The human interface panel monitors all parameters for the bottle washer, as shown in Figure 177.3b.
Figure 177.1. Bottle washing process stages.

Source: Author.
Figure 177.2. Water distribution in bottle washer compartments.

Source: Author.
Figure 177.3. (a) Pressure sensor, (b) Human machine interface (HMI).

Source: Author.

2.2. Water consumption calculated

For most beverage and alcohol industries, water consumption is measured in hectoliters (HL) based on the amount of water used by a piece of equipment compared to the amount of product produced (HL). In this case study, beer production is measured in hectoliters (HL).

$$\text{Water Consumption (HL/HL produced)} = \frac{\text{Volume of Water Used (HL)}}{\text{Volume produced (HL)}}$$

The target consumption for bottle washer is 1HL/HL produced. Daily (24 hours), the utility technician collects consumption figures around the brewery, including the water consumption in the bottle washer. Data is then reported into a database in Figure 177.3b.

3. Methodology

To enhance the robustness of the research and achieve the study's aim [2, 6], we decided to utilize a mixed-method approach involving both qualitative and quantitative methods focused on a single case study. This type of research has the following characteristics:

a) Large sample size: Consumption data were collected from a 2018 data source for eight months.
b) Numerical outcomes [4]: Data were collected from a system.
c) Generalized outcomes: Large samples of consumption were taken, and decisions can be made [4].
d) Identification of failure modes through observation and troubleshooting.

The paper demonstrates the practical application of Root Cause Failure Analysis, a process used to identify the actual root cause of a specific failure and utilize that information to determine corrective/preventive actions [7, 9]. This analysis involves techniques such as the 5 Whys against the framework for 4M (Man, Method, Machine, and Material). The method, created by Sakichi Toyoda, emphasizes asking "why" five times or until the root cause of the problem is found.

The root cause failure analysis process used in this project is based on the Heineken Unified Problem-Solving approach (UPS). This approach consists of five key steps. First (a), the process starts with a thorough problem description to clearly define the issue. Then (b), efforts are focused on understanding and restoring the basic conditions surrounding the problem to provide a strong foundation for further analysis. The third step (c) involves conducting a root cause analysis using the 5Why method, which involves asking "why" repeatedly until the fundamental cause of the problem is identified. Once (d) the root cause is determined, appropriate countermeasures are developed and implemented. This is followed by careful follow-ups to assess their effectiveness and address any remaining issues. Finally (e), successful solutions are standardized, and the learnings from the process are shared through a structured rollout to ensure that similar problems can be efficiently addressed in the future. By following these systematic steps, the root cause failure analysis process aims not only to resolve immediate issues but also to prevent their recurrence, contributing to continuous improvement and operational excellence [5–10].

4. Results and Discussions

4.1. Problem description

During the first step of the process, we carefully described the issue of high-water consumption in the bottle washer. We took two primary actions to achieve this. Firstly, we established a data collection system by building upon an existing infrastructure within the utilities department. We systematically collected and organized data related to water usage, which helped us gain a comprehensive understanding of the problem. This data was then documented in Table 177.2 for reference and analysis. Secondly, we analyzed historical data and set performance indicators to measure the efficiency of the bottle washer. For water consumption, we defined the indicator as 1 hectoliter (HL) of water consumed per HL of bottles produced. Over a period of five months, we analyzed the collected data and identified trends indicating high water consumption in Table 177.1 and in Figure 177.4. Specifically, we calculated the average consumption for the bottle washer to be 1.21 HL per HL produced, highlighting a significant deviation from optimal levels. By meticulously examining both the collected data and performance indicators, we established a clear understanding of the problem's scope and severity, laying the groundwork for subsequent analysis and remediation efforts [1–5].

4.2. Restore the main conditions in essential areas and establish standards

During this phase, the team focused on gaining a deep understanding of the bottle washer and identifying areas where water usage could be high. They started by pinpointing critical areas or potential issues that could lead to increased water usage. To do this, the team used the Ishikawa method, also known as cause-and-effect analysis, developed by Kaoru Ishikawa in 1960. This structured approach allowed the team to systematically examine various factors and potential root causes, leading to a comprehensive assessment of the bottle washer system. The findings of this analysis were recorded and organized in Table 177.2, providing a visual reference for further investigation and problem-solving. By applying the Ishikawa method, the team gained valuable insights into the complex factors affecting water consumption in the bottle washer, setting the stage for future diagnostic and corrective actions [8–10].

All possible functional failures were examined and narrowed down to only five. Their failure modes were also identified, and corrective actions were taken as shown in Table 177.3.

The main issues we observed were related to the T-Sieve being frequently drained and cleaned during production, which is not necessary under normal operating conditions. This led to blockages in the T-Sieve, a crucial strainer designed to prevent large particles from entering the preheating sprayers during the pre-rinse stage.

Table 177.1. Consumption volumes for bottle washer and volumes for beer produced

Months	Volume washer (m³)	Volume (HL)	Volume Produced (HL)	Consumption (HL/HL Bottle)
Jan	1128	11280	09839.2	1.15
Feb	1193	11930	10026.4	1.19
Mar	1008	10080	07343.3	1.37
Apr	0929	09290	07816.8	1.19
May	1462	14620	12690.6	1.15
			Average	1.21

Source: Author.

Another problem was that operators were conducting unnecessary runouts during extended stops before the washer, resulting in water loss as empty carriers were washed at the discharge. This action was not part of standard production procedures and was due to operators' lack of awareness regarding its impact on water consumption.

We also found that three baths at the post-rinse stage were being drained during production when

Table 177.2. Show the possible causes

Man	Method	Machine	Material
Zone 1 and 2 cleaning of Strainers	Machine Speed (New/Old)	minor stop/tailback/BD	Dirty Glass
Runout During production	Cleaning frequency	Additive dosing	Crown m bottles
Infeed speed (FB)	caustic dosing procedure	fallen bottles (Depal and Conveyor)	supplier (Bottle)
Manual valves	caustic refresh/ sedimentation	freshwater monitoring pump	
Caustic bath	Runout procedure	(error on HMI)	
Pre-wash	new glass/old glass	Caustic freshwater valves (Pneumatic)	
Purge line frequency	change between shifts and supplier	Glass Type selection (Fresh Water spray)	
Depal Operator (Bottle Starvation)			
Drain out final rinse zones + refill due to caustic present in bottles			
Prewash draining frequency

Table 177.3. Functional failure and failure mode for high water consumption in bottle washer

Functional Failure	Failure Mode	Corrective Actions
Zone 1 and 2 cleaning of Strainers	Blockage of T-sieve at preheating-submersion baths	Clean all T-Sieve
Runout During production	Operator not aware of the effect of running in empty carriers	Runout During production is stop and awareness made to the operators
Drain out final rinse zones and refilling due to caustic present in bottles	No proper method for draining zones when caustic is present in bottles	Create procedure for draining
Frequent overflow and adding of water to bath 3	Faulty Level Sensor	Faulty Level sensor was replaced
Washing Empty Pockets during startups	No procedure available for running empty pockets during startup	Create startup procedure for running empty pockets

Source: Author.

chemical residue was present in the bottles at the discharge. However, the absence of a defined draining procedure led to inefficiencies in water usage.

Additionally, there was a problem with detergent bath 3's automatic refilling when its level dropped below the safety limit indicated by the Human Machine Interface (HMI). A maintenance technician identified a faulty pressure sensor that triggered unnecessary refilling even though the baths were above the designated safety level.

Finally, we noted that empty carriers were being washed during startup, leading to increased water consumption. With a total of 494 carriers, each equipped with 47 pockets for bottles, empty carriers traversed the freshwater zone in the post-rinse compartment during bottle feeding at startup.

These functional failures collectively resulted in heightened water consumption over the five-month period. Remedial actions for each failure included implementing procedural protocols, replacing faulty components, and enhancing operator awareness, as detailed in Table 177.3.

4.3. Root cause analysis

In this step, a five-why analysis is carried out for each failure mode to identify the root cause for each failure mode. The root cause is directly linked to the following four (Man, Method, Material, and Machine). The failure modes and their respective root causes are as follows: the blockage of the T-sieve at preheating-submersion baths is attributed to an ineffective cleaning procedure for the T-sieve; operators' lack of awareness regarding the impact of running empty carriers stems from inadequate training and awareness programs on the importance of water usage; the absence of a proper method for draining zones when caustic is present in bottles results from the lack of a defined procedure for draining; a faulty level sensor is caused by the absence of a proper calibration maintenance schedule; and the absence of a procedure for running empty pockets during startup is due to insufficient awareness regarding the consequences of running empty carriers during startup (See Table 177.4).

4.4. Countermeasure

In this step, a countermeasure or preventative measure was generated for each root cause to eliminate it. The countermeasure was implemented and monitored over a period of four months to measure its effectiveness. The ineffective cleaning procedure for the T-Sieve can

Table 177.4. Failure mode and root causes for high water consumption in bottle washer

Failure Mode	Root Cause
Blockage of T-sieve at preheating-submersion baths	ineffective cleaning procedure for T-Sieve
Operator not aware of the effect of running in empty carriers	No awareness and training on the importance of water usage
No proper method for draining zones when caustic is present in bottles	No procedure for draining in place
Faulty Level Sensor	No proper calibration maintenance schedule in place
No procedure available for running empty pockets during startup	No awareness done on running empty carrier during startup

Source: Author.

be addressed by establishing a comprehensive cleaning standard specifically for cleaning strainers in the preheating stage and providing thorough training to operators on its implementation [10, 11].

To tackle the lack of awareness and training on the importance of water usage, initiatives should be undertaken to provide training and raise awareness among operators regarding the significance of water conservation, particularly when running empty pockets. Additionally, the absence of a draining procedure can be remedied by implementing a draining standard for the final rinse zone when caustic is present in the bottles, accompanied by the installation of pH probes to monitor water pH levels.

To ensure proper calibration and maintenance of sensors, a maintenance schedule should be established to regulate the upkeep of pressure sensors and level transmitters across all baths. Lastly, addressing the lack of awareness regarding running empty carriers during startup can be achieved by implementing a procedure mandating the completion of 460 cycles before opening the freshwater valves during startup, resulting in substantial water savings of 52.6HL on a weekly basis. Table 177.5 summarizes the root causes and their countermeasures [9].

4.5. Standardize and roll out

After confirming the effectiveness of the countermeasures, they were standardized and prepared for implementation in other bottle washers. A monthly inspection for all level sensors was added to the CMMS system to

Table 177.5. Counter measure for each root cause

Root Cause	Countermeasure
Ineffective cleaning procedure for T-Sieve	Create cleaning standard for cleaning strainers in the preheating and train operators how to use
No awareness and training on the importance of water usage	Training and awareness in place for the impotence of water consumption when running empty pockets
No procedure for draining in place	Draining standard for final rinse zone when caustic is present in the bottles and pH probe installed to sense the pH of the water
No proper calibration maintenance schedule in place	Maintenance schedule is in place for maintaining pressure sensors and level transmitters for all baths
No awareness done on running empty carrier during startup	Procedure in place for running 460 cycles before opening the freshwater valves. Saves 52.6HL on every weekly startup

Figure 177.5. Consumption of bottle washer (HL/HL Bottled).

Source: Author.

ensure regular monitoring and address the root cause of the lack of a proper maintenance system. The RCFA was conducted on the bottle washer equipment at SP Brewery Lae as outlined in the methodology. From January to May 2018, there was an increase in water consumption, as shown in Figure 177.4. However, after the RCFA and the subsequent implementation of countermeasures in late May and early June, there was a significant improvement [11-13]. This improvement was sustained from June to September 2018, as demonstrated in Figure 177.5. An average water consumption rate of 1.03 HL/HL was achieved, indicating a reduction of approximately 74%.

5. Conclusion

The root cause failure analysis conducted to address high water consumption in the bottle washer equipment was successful in 2018. The research effectively achieved its objective of identifying countermeasures to mitigate high water consumption using the root cause failure analysis method. The failure modes and root causes contributing to high water consumption were identified in steps 2 and 3 of the analysis. Tailored countermeasures were developed for each identified root cause in step four, ultimately bringing the bottle washer's consumption within the target range. While this study focused on water consumption in bottle washer equipment, it demonstrates the versatility and efficacy of the root cause failure analysis method, which can be applied to solve a diverse array of problems across various industries and contexts.

178 Investigation of Absent Imprints in Laser Date Coding for Cans

Aezeden Mohamed[1,a] and Sacchi Noreo[2]

[1]School of Mechanical Engineering, PNG University of Technology, Lae, Morobe, Papua New Guinea
[2]South Pacific Brewery Heineken, Morobe Province, Lae, Papua New Guinea

Abstract: This case study investigates the phenomenon of missing date prints on cans at SP Brewery Manufacturing Company, despite the activation of their cutting-edge Can Date Coder system. Through a structured methodology involving data collection, analysis, and verification of countermeasures, the root causes of the issue were identified, including misalignment of sensors, clogged filters, and lens issues. A series of countermeasures were implemented, resulting in a reduction of occurrences during a trial period in 2024. Based on the findings, recommendations for a preventive maintenance system and standardized pre-startup checks are proposed to ensure consistent and accurate date coding in the future. This study highlights the importance of proactive maintenance and continuous improvement in enhancing operational efficiency and product quality in manufacturing environments.

1. Introduction

SP Brewery Manufacturing Company has a cutting-edge date coding system, the Can Date Coder, to enhance efficiency and accuracy in their packaging operations. However, they encountered a perplexing issue where the laser beam appeared to be functioning correctly, but some marking results were not printed on the can. This case study aims to investigate causes of miss prints and propose counter measure. A number of cases related to the same issue between 2020 and 2024 were reviewed.

The case study revolves around South Pacific Brewery Ltd canning production line. The company utilized e-SolarMark 30 and e-SolarMark Laser coder equipment for its production processes. This equipment plays a crucial role in quality control and production monitoring, ensuring that the brewery maintained high standards of date coding. Below is a flow of canning line process and where the laser coder is located (Figure 178.1).

Despite the laser beam being activated, some dates on the cans were not printed with the intended information. The production team noticed inconsistencies in the placement and legibility of the markings, leading to potential quality control issues and delays in the packaging process.

2. Methodology

2.1. Data collection

Incident Reports: The reports of incidents where cans were missing date prints. These reports include the breakdown time, frequency of breakdown, and the can coder. The Incident reports provided essential data points for identifying patterns and trends related to the issue.

Interviews and Observation: Conducting interviews with operators, maintenance personnel, and quality control staff to gather qualitative data on potential causes and observations related to missing date prints. Additionally, direct observation of the laser coding process allows for real-time insights into operational practices and potential areas of improvement.

2.2. Data analysis

Review of Past Activities: Analyzing historical data, including operational logs and maintenance records, to identify any recurring issues or trends associated with missing date prints. This involves examining past incidents and maintenance activities to understand their impact on the printing process.

---

[a]aezeden.mohamed@pnguot.ac.pg
Figure 178.1. Canning line process flow.

Source: Author.

Identify Deviations: Comparing data from normal operation periods with instances of missing prints to identify deviations or anomalies. This analysis helps pinpoint specific factors or events that may have contributed to the breakdown in the laser date coding system.

2.3. Verification of countermeasure

Trial Run of Proposed Countermeasures: Implementing a pilot test of the proposed countermeasures on a small scale to evaluate their effectiveness in preventing missing date prints. This trial run allows for practical validation of the countermeasures before full-scale implementation, helping to refine and adjust them as needed based on real-world performance and feedback. Case Study Implementation.

3. Data Collection and Findings

Incident report: Table 178.1 shows frequency of events that happened with missing date coding on cans. This were occurrence that caused halt in the production. There were other instances but was not recorded. Figure 178.2 demonstrates the frequency in years from 2020 incident and 2024 similar incident.

Interviews and Observation: During qualitative interviews conducted with technicians familiar with the issue, several possible causes for missing date prints on cans were identified. These included misalignments of the trigger sensor, which could prevent accurate detection of cans and initiation of the printing process. Additionally, the height adjustment of the air blower

Table 178.1. Incident report on missing date coding on cans

Incidents ID	Occurrence Date	Issues
1	03/8/2020	Dates not printed correctly
2	12/7/2020	Date coding not printed
3	02/9/2024	Cans missing date marking
4	2/10/2024	Cans missing date marking
5	03/6/2024	1/every 10 cans not marked/coded
6	03/7/2024	1/every 10 cans not marked/coded

Figure 178.2. Representation of incidents of missing prints on the can.

Source: Author.

was considered a potential factor; if not properly set, it might disrupt the alignment or stability of cans during printing. Coding head adjustment emerged as another likely cause, as any misalignment or calibration issues could lead to inaccurate or inconsistent application of date prints. Furthermore, clogged filters were highlighted as a significant concern, as they could obstruct necessary airflow or other elements within the coding system, resulting in incomplete or irregular printing. Figure 178.3 shows the possible causes.

This Table 178.2, clearly depicts the incident ID, Occurrence Date, Issues, and Failure Mode.

4. Verification and Testing

To address the identified issues and failure modes, the following countermeasures have been implemented. Firstly, the prefilter has been replaced, and the extractor unit has been thoroughly cleaned to mitigate the problem of blocked filters and fume extractors, ensuring smoother operations. Additionally, efforts have been made to realign the position for troubleshooting purposes, allowing for more effective identification and resolution of underlying issues. Moreover, cleaning and replacement of the lens have been conducted

3	02/09/2024	Troubleshooting in progress
4	02/10/2024	Clean and replaced Lense
5	03/06/2024	Troubleshooting in progress
6	03/07/2024	Adjustment on speed settings of conveyor and guides

Source: Author.
Figure 178.4. Relationship between trial number and the number of missing prints on countermeasures.

Source: Author.

to rectify discrepancies in date printing. Furthermore, adjustments have been made to the speed settings of the conveyor and guides, aiming to optimize the production process and minimize errors in date marking. These countermeasures collectively contribute to eliminating the missing print in the laser coder system, ensuring consistent and accurate date marking on the products. Table 178.3 provides comprehensive details on the incident ID, including the unique identifier assigned to each incident, the occurrence date, which denotes the date when the incident took place, and finally, the countermeasure, describing the specific actions taken to address the incident.

Figure 178.4 below shows the implemented countermeasure trial carried out in 2024. There were 18 trials carried out when implementing the countermeasures. It was noted that on trial 16 to 18 there was not occurrence of missing prints hence the countermeasure was taken note of.

In light of the conducted trials, we have finalized the proposed countermeasures for implementation. Our preventive maintenance system encompasses monthly inspection and cleaning of coder lenses, routine inspection and cleaning of filters, and the establishment of a centralized point for lesion creation, along with training on troubleshooting procedures in Figure 178.5.

Figure 178.5. (a) Coder, (b) Air blower, (c) Date inspection.

Source: Author.

Moreover, prior to commencing operations, it is imperative to ensure that the laser unit is activated and functioning, confirm the operational status of the can dryer, and execute test runs using sample cans to validate their performance.

5. Conclusion

In conclusion, the investigation into the perplexing issue of missing date prints on cans at SP Brewery Manufacturing Company has yielded valuable insights and actionable solutions. Through a comprehensive analysis of incident reports, interviews, observations, and data, several potential causes and failure modes

were identified, ranging from misalignment of trigger sensors to clogged filters and lens issues. To address these issues, a series of countermeasures have been implemented, including replacing filters, cleaning extractor units, realigning positions, and adjusting conveyor speed settings. A trial of these countermeasures in 2024 demonstrated promising results, with a notable reduction in occurrences of missing prints towards the end of the trial period.

Moving forward, it is recommended to finalize and implement a preventive maintenance system, which includes regular inspection and cleaning of coder lenses and filters, as well as establishing standardized pre-startup checks to ensure the proper functioning of equipment before production runs. By proactively addressing potential issues and maintaining equipment, SP Brewery can enhance efficiency, minimize downtime, and ensure consistent, accurate date coding on their products.

5.1. *Recommendation*

1. Conduct a thorough investigation of the vacuum unit and cooling unit for any abnormalities or malfunctions that may contribute to the issue of missing date prints on cans.

2. Implement a protocol for cleaning the filter unit before every startup to prevent clogging and ensure smooth operation of the Can Date Coder system.

3. Provide comprehensive training to operators and maintenance personnel on the working principles of the Can Date Coder system, including troubleshooting procedures, to enhance their understanding and ability to identify and resolve issues effectively.

179 Experiment on the impact of resin matrix under static and fatigue stress in basalt fiber reinforced polymer composites

Madhu Sahu[1,a] and Abhay Dahiya[2,b]

[1]Assistant Professor, Department of Civil Engineering, Kalinga University, Raipur, India
[2]Department of Civil Engineering, Kalinga University, Raipur, India

Abstract: Experimental research was done to determine the static and fatigue characteristics of various resin matrix-based BFRP composites in order to shed light on the behaviour and damage process of BFRP (basalt fibre reinforced polymers). In this research, two kinds of resins were used. They were (Vinyl Ester) VE resins, normal and toughened. The fatigue test apparatus was used to observe damage concurrently with the static and fatigue testing. The findings demonstrated the significant roles that the resins had in the fatigue and static behaviour of BFRP composites. The typical VE resin-based BFRP's static tensile strength. However, because more matrix cracking and fibre peeling happened on the surface of the BFRP based on VE resin, the former's fatigue life was much shorter than the latter's. With more ductile matrix, such as Toughened Vinyl Ester (TVE), the BFRP's static strength was lower; nevertheless, as the resins' fracture expansion grew, so did the BFRP's long-term fatigue strength (FS) level.

Keywords: Resin matrix, static stress, fatigue stress, basalt fiber, reinforced polymer composites, BFRP, mechanical performance, composite materials, fatigue life, ultimate tensile strength

1. Introduction

Basalt fibre reinforced polymer (BFRP) is gaining popularity due to its superior mechanical qualities and lower cost compared to glass fibre reinforced polymer (GFRP). BFRPs have greater creep and fatigue characteristics than GFRP composites [1-3], making them suitable for constructions prone to fatigue loads [23]. However, fatigue properties vary among matrices [4-7]. Studies have examined the impact of resin on the fatigue and mechanical properties of FRP laminates. For example, studies by Rassmann et al. compared the water absorption and mechanical behaviour of polyester, VE, and epoxy laminates reinforced with kenaf fibre and glass fibre [8]. Colombo et al. found that basalt reinforced epoxy composites had superior mechanical characteristics [9]. Research indicates that the fatigue behavior of fibre reinforced polymers (FRPs) is influenced by the matrix's characteristics, and using toughened resins can enhance this behavior [10–13]. However, pultruded materials such as wires,

profiles, or BFRP tendons are often not suitable for the resins used for FRP laminates [22]. This study aims to assess the impact of resins on fatigue, static behaviour, and damage processes of BFRP composites to optimize the resins used in pultruded fatigue-sensitive structural parts [14]. Two types of resin-based BFRP composites were analyzed using modern fatigue testing equipment. The resins tested, including regular VE and TVE, were found to be fitted for pultruded materials like BFRP tendons. Figures 179.1 and 179.2 shows the basalt finer and vinyl ester resin.

2. Material Characteristics

The study evaluated continuous longitudinal basalt fibre reinforced composites using basalt fibres treated with silane sizing [15]. The composites showed tensile strength, Modulus of elasticity, and fracture expansion at Two Thousand Four Hundred MPa, Ninety GPa, and 2.2%, respectively. Two varities of resins used: Reichhold Polymers' Corrolite 9102-70 Sino

Figure 179.1. Basalt fiber.

Source: Author.

Figure 179.2. Vinyl Ester Resin.

Source: Author.

Polymer Co.'s TVE MFE-9, and the standard VE. The TVE showed significant improvement in strength and expansion compared to the standard VE. However, it was strengthened with elastic nanoparticles, which could prevent tiny cracks.

The experiments involved pre-impregnated basalt fibre bundles and end tabs, which were twisted onto a flat mould to create a continuous bundle measuring 3 mm in width and 0.25 mm in thickness. With four end tabs secured to the bundle, the gauge length measured twenty millimeters.

The specimens were post-curred, chilled in air, and chopped into 70 mm long dumbbell shapes. They were prepared and transferred hydraulic servo fatigue drive for quasi-static and fatigue testing. The load providing, values noting, and gripping devices used in the study were the same as those used in the authors' prior works, which were shown to be appropriate for evaluating BFRP composites [13, 21]. The quasi-static testing involved five replicates of fiber yarn (FRP) specimens at a stroke rate of two millimetres per minute, while fatigue investigations were conducted beneath a cyclic load at normal room temperature or atmoaphere. The stiffness of the specimens was measured during each fatigue loading cycle, and the results were recorded.

Table 179.1. Characteristics of Resins

Resins	Tensile trength (MPa)	Modulus of Elasticity (Gpa)	Fracture Expansion (%)
Normal VE	44.80	3.12	1.56
TVE	67.40	2.94	5.39

Source: Author.

3. Results and Discussions

3.1. *Static tensile characteristics*

The static strength of BFRP with different resin matrix compositions exceeds 2300 MPa, significantly lower than carbon fiber reinforced polymer sheets but more than E-glass FRP sheets [18]. The lowest strength was found in toughened vinyl matrix-based composites, accounting for only 84% of the maximum strength in typical VE BFRPs. BFRP strength reduced as fracture expansion rose in the matrix, possibly due to a drop in density of cross linking toughened systems [16, 17]. The tiny BV specimens in this investigation allowed for uniform load distribution and good anchoring in Table 179.1. BFRP stress-strain curves (excluding BV) were linear with a sharp decrease behind failure, as characteristic of a FRP stress-strain curve. When the BV specimens neared maximum force, there was a noticeable rise in displacement without a considerable load drop, implying that the vinyl specimen failed due to unequal fibre fracture and peeling. The specimens macroscale fracture exhibited a broom-like looks, with fibres blasted out, which is the preferred fracture pattern for static testing.

The VE matrix ruptured, causing fibres to separate into loose ones. The specimen, small and anchoring, held each fiber together. Despite fibre peeling, the specimen could carry weight. In hardened VE-based BFRP, fibres were blasted off, but undamaged matrices remained visible, indicating decreased matrix breaking.

3.2. *S-N curves*

The fatigue tests on BFRP composites revealed varying fatigue life lengths due to statistical variances in rate of failure or damage. These findings are distinctly dispersed, as predicted for FRP composites. The least-square approach was used to estimate linear fitting S-log(N) correlations from investigation findings.

$$\sigma_{max}\frac{1}{4} = A\log(Nf) + B \qquad (1)$$

Table 179.2. Test programs

Specimen	Matrix	Curing Conditions	Ratios for stress	Frequency	Run-out
BV	Normal VE	Two hours five minutes 201°C	0.85	10 HZ	1×10^7
BRV	TVE	Two hours five minutes 201°C

Table 179.3. Ultimate tensile Strength (UTS) of different resins based BFRP

	BV	*BRV*
Mean Value of UTS (MPa)	2655	2236
COV %	4.93	3.61

Source: Author.

where σ_{max} presents the highest stress due to fatigue, N_f presents the respective number of cycles to failure, and the model dimensions that will be acquired are A and B by the available fatigue findings in Table 179.2. The curve fitting process excludes data pertaining to specimens that failed the fatigue testing [19].

Table 179.4 shows fitting findings, with coefficients of determination less than 0.9 due to damage pattern shifts for high-cycle and low-cycle fatigues in Table 179.3. BV specimens showed the sharpest slope of the S-N fatigue curve, indicating the quickest rate of FS reduction over fatigue life. The BFRP based on toughed VE resin (BRV) had the smallest absolute value of dimensions A, indicating enhanced fatigue qualities. S-N Curves For several resin-based BFRPs, there were differences in the static tensile strengths. The linear fitting stress levels–log (N) correlations derived from investigation findings utilizing the east-square approach in accordance with Eq. (2) are, normalised with the tensile strengths.

$$r_{max} = \frac{\sigma_{max}}{\sigma_{ult}} = Ar\,log\left(\mathbb{N}_f\right) + B_r \tag{2}$$

The model parameters, Ar and Br, are established by the available fatigue data, and r_{max} maximum the stress level (ratio of maximal fatigue stresses, σ_{max}, to ultimate strength, σ_{ult}), denotes the respesctive number of cycles to failure, N_f. indicates a respective number of failure cycles. The study focuses on fatigue resistance of BFRP materials, specifically BRV, using fatigue data and S-N curves. The results show that toughened BRV specimens have a longer life than BV specimens at the same stress levels, and the difference in life durations increases as stress levels decrease. The fatigue degradation process is further explored, and the S-N curves can be used to forecast the FS and life of various resin-based BFRP materials. TVE-based BFRP has lower FS compared to vinyl matrix-based BFRP due to decreased static strength. However, when static strength is used to normalize fatigue performance, the FS level for ten million cycles rises from seventy to seventy six percentages The FS findings for BRV materials are greatest due to the lowest slope of the S-N curve for longer cycles.

3.3. *Stiffness degradation*

Stiffness degradation is a marker for damage sustained initial fatigue force, which can be categorized into three areas: a greater number of cracks initiation within the first twenty percentage of fatigue life, slow and stable crack growth along the fiber-matrix interface, and fibre breaking just before failure [11, 13] the results primarily reflect the three-region model. The hardened BRV specimen showed a noticeable decrease in stiffness deterioration at twenty percentage of the fatigue life in differentiated to the BV specimen that was not toughened, indicating a lower crack dam age [20]. However, the difference in area I was negligible, as the fiber primarily contributes to stiffness in unidirectional BFRP. At ninety percentage of fatigue life, BRV showed more deterioration than BV, indicating that more ductile BFRP matrices were more resistant to damage.

3.4. *Fatigue damage mechanism analysis*

The typical VE matrix to break and for the fibre to peel off in BV under fatigue loading. During fatigue cycles, the peeled off fibres in the BV sample progressively stopped operating. More fibres peel off as a result, increasing the cyclic strain [21]. The BV specimens failed when the remnant fibres' real stress reached their breaking point. The fatigue failure processes of fiber-reinforced polymers can be influenced by the ductility and cracking of the polymer matrix, and the long-term fatigue limit of a unidirectional composite is roughly the fatigue limit of the matrix [10–12]. Polymer matrix expansion causes the slope of the S-N fatigue curve to increase. A lower rate of fatigue life and early stiffness deterioration may arise from this lesser and less severe fatigue damage.

4. Conclusion

Using static and fatigue testing, the impacts of the resin matrix on the BFRP's static characteristics, fatigue behaviour, and damage mechanism were examined in

Table 179.4. Greatest fatigue force S-N curves based on two VE Resins

Specimens	Parameters		Coefficient of Determination R^2
	A	*B*

this work. In the test, two distinct kinds of BFRP composites with a resin foundation were used. These are VE resins, regular and toughened. The following is a summary of this paper's main findings:

1. The BFRP static strength based on vinyl resin was ascertained. For vinyl resin-based materials, failure mechanisms of fibre peeling and fibre pull-out are identified. While the peeled off fibres progressively stop working under a cyclic stress, they may support a static load with strong end anchoring.

2. It is evident that under static and fatigue stress, the increased ductility of the BFRP polymer matrix can inhibit the growth of matrix cracks. More ductile matrix-based BFRP, like BRV, has a longer long-term fatigue life and residual stiffness than BV because it is more ductile and has less fractures. Before and after toughening, the vinyl resin-based BFRP's 10 million cycle FS level rose from 69.89% to 75.56%. Nevertheless, BRV specimens had lower static strength and short-term fatigue life than BV specimens.

3. For all studied resin types, the S-N fatigue curve slope rises as resin matrix expansion increases. Matrix expansion and cracking can regulate the BFRP composites' long-term fatigue limit.

Based on a small set of data, the study's findings, which demonstrate a distinct resin influence on BFRP's long-term fatigue life, are presented. Additional research would be useful to measure these impacts and offer additional direction on enhancing the fatigue life of BFRP materials. In the future, a more appropriate matrix may be researched and used to BFRPs to extend the fatigue life of BFRP cables, bridge decks, and other goods.

180 Characterization of polymer ceramic composite materials for orthopedic applications

Gaurav Tamrakar[1,a] and Swapnil Shuklaistant[2,b]

[1]Assistant Professor, Department of Mechanical, Kalinga University, Raipur, India
[2]Professor, Department of Mechanical, Kalinga University, Raipur, India

Abstract: This article reviews the various orthopedic applications of polymer composites. The article covers a number of composite properties along with their purposes, goals and specific uses. This study highlights the advantages of currently used composite and graft materials. The specific use of polymers in the field of orthopedics is the main subject of this literature. The continuous development of bone healing technology is necessary to create new materials with improved functional and technological properties. The creation of composite materials for bone regeneration that incorporate ceramics and polymers is one exciting field of study. These materials provide several advantages over traditional bone graft materials, including the ability to adapt to the specific needs of each patient and reduce the risk of disease transmission. Significant advancements have been achieved in the creation of polymer-ceramic biomaterials with enhanced bone regeneration potential in recent times. This work mostly focused on improving mechanical properties, biodegradability and biocompatibility. The aim of this review is to provide a summary of the latest advances in composite ceramic polymers for bone regeneration, including the components used in these biomaterials and related manufacturing processes.

Keywords: Surface morphology, in vivo compatibility, ceramic fillers, tissue engineering, polymer matrix composites, nanocomposites, orthopedic implants

1. Introduction

Modern technologies and artificial gadgets contribute to the development of biomaterials. Nowadays, biomaterials have improved biocompatibility and work in tandem with the body. In [1, 2] there are references to the attributes and structure of biomaterials. The remarkable properties of these materials, such as strength-to-weight ratio and high biocompatibility, are highlighted in [3] and [4, 5].

Aspects such as cost, practicality and biocompatibility are also included. Finally, referring to the principles of bone remodeling described in "Wolff's Law", "Bone is deposited and strengthened in areas of greatest stress" [6].

- Bioinert materials of the first generation, also known as biologically inert materials.
- Bioresorbable materials (third generation); bioactive materials, also known as biologically active materials (second generation).

Especially in hard tissue applications, first-generation materials are still widely used and more and more research are being done in this area. The goal of second and third generation materials is to develop innovative treatment approaches. Composites have been found to be advantageous for complex development in this way. Third generation materials are adapted to specific biological reactions [7, 8]. They create biodegradable frames and ordered systems [8–10]. It is also important to note that before these materials are approved for use in commercial and surgical settings, they must first undergo rigorous tests and trials [5]. A brief overview of next-generation biomaterials targets is included, along with an overview of some of the most important recent findings [21]. Ed for bone regeneration, including materials used in these biomaterials and related manufacturing methods.

2. Tissue Engineering in Practice

Prospects for soft tissue engineering are associated with the production of bone scaffolds specifically associated with bone tissue engineering. Autografting and allografting are two methods used to treat defective bone. Today, the main areas of research are

osteoconductivity, osteoinductivity and, above all, biocompatibility. Biomaterials are often used in conjunction with drugs and antibiotics to promote healing and prevent infection. The present bone tissue provides many advantages:

- Skeletal cells of the donor tissue grow faster.
- Defective bone can be replaced with a suitable biomaterial.
- Stem cell therapy can make it less likely that a patient's life will be in danger.

3. Application in Orthopedics

In the field of orthopedics, biomaterials are highly sought after. This is undoubtedly advantageous for research and commercialization, and tests are being conducted to improve the performance of previously deficient bones by studying and experimenting with composite materials. HAPs with porous architectures that offered better bonding to bone were the subject of a recent study [20]. Using calcium nitrate $[Ca(NO_3)_2 4H_2O]$ for calcium and potassium dihydrogen phosphate $[(NH_4)_2HPO_4]$ for phosphorus as a precursor, a hydrothermal method was employed to create the HAP powder.

3.1. Bone grafting

In summary, microscopic observations of bone reveal the cellular structure of matrices and osteocytes. Collagen fibers provide a matrix that gives bone strength and elasticity, while HA microcrystals and mineral salts contribute to bone hardness. Bone remodeling is a process of continuous replacement and remodeling of bone tissue. Stimulation of osteocytes helps to initiate remodeling of osteoblasts and osteoclasts, which is also dependent on the level of applied stress. Similar to allografts, autografting of defective bone has its limits and is an ongoing research topic. The research was carried out on composites, where the graft consists of demineralized bone powder inserted between two layers of collagen.

The test demonstrates cell migration and is performed both in vitro and in vivo.

As a layer of HA on broken bones, bioactive ceramics help to accelerate the production of osteoblasts that promote bone repair. Studies also suggest the use of high-density polyethylene (HDPE) and HA layer together as a bone substitute material. After testing, it was given the trade name HAPEXTM. Typically, the range of HA is taken to be in the range of 20–40% by volume. According to empirical data, osteoblast terminated the bioactive ceramic layer of HA particles. Collagen fibers and HA particles mixed with bioactive ceramic composites may one day replace natural bone. The graft has also been shown to have good

mechanical properties [11]. It has been proposed to use HA/alumina as a bone substitute [12]. In addition, the study concluded that the addition of HA particles to P_2O_5 glass mimics the properties of real bone [13]. Additionally, studies suggest that the use of partially resorbable composites composed of a polymer matrix—such as PEG, PBT, PLLA, PHB, alginate, and gelatin—improves outcomes [22]. Bone replacement is enabled by HA particles working in tandem with a polymer matrix that exhibits covalent bonding [14]. The effect of HA content was observed using elastomeric copolymers of D,L-lactide and ε-caprolactone (60/40 ratio) reinforcing HA powder [15].

The combination of HA with bioactive ceramic TCP provides us with the additional material needed to create artificial bone [16]. Coupling agents can be used to obtain high modification.

The cross-linking of glutaraldehyde in the composite should be less than 8% to prevent suppression of cell proliferation by reducing the cytotoxicity of cytoblast cells [17, 18].

TCP has also been used in conjunction with biodegradable PP as a temporary trabecular bone substitute [19].

When examined, it was found that the composites retained modulus and compressive strength higher than the minimum value of trabecular bone replacement. In addition, biomaterial substitutes have been revolutionized by bioglass technology. 37% by weight of bioactive glass powder, 27% by weight of PLA, 27% by weight of PMMA and 9% by weight of antibiotics were used to create the composites [20]. Although the long-term consequences are still being investigated, in vitro experiments have shown desirable results by forming an apatite-like layer on the composite. A PE matrix was also used for bioglass.

Although the composite has poor adhesion to the matrix, it has excellent mechanical and osteoconductive properties and integrates more quickly into bone tissue. In addition, in vivo tests on carbon fibers revealed that the porosity of the material is the cause of tissue-implant adhesion. Another composite, which is primarily composed of collagen and $CaCO_3$, has been tried and used to treat damaged bone without the need for infections.

3.2. Bone fracture repair

Bone fracture repair involves a variety of techniques; typically, this is external attachment internalization. Casts, braces, and other external fixation devices—or any other type of fixation system—maintain bone alignment. Materials were previously constructed from cotton and salt plaster. Breath free casts were created to prevent peeling of the patient's skin. Doctors can now easily obtain and use carbon fiber casts

that are incredibly light due to the latest technological advances. By reinforcing the plastic with carbon fibers, walking speed, dexterity and gait are increased. Bone fragments are held in place during internal fixation with implants such as plates, screws, wires, and pins.

There are two groups of compound composites: avital/vital and vital/vital.

The "non-living" matrix forms vital/vital composites, while the "living" matrix forms vital/vital composites.

- A third classification for avital/vital composites is absorbable
- absorbable to some extent
- Fully absorbable mixtures.

Resorbable bone plates cause a slow increase in bone stress that worsens as the bone heals; perhaps as a result there is less bone to protect against stress, preventing osteopenia. Physicians have adopted and used a variety of resorbable polymers, including PLLA, PGA, and PGLA. It has good mechanical properties and a slow rate of deterioration; to improve the quality, fibers were added to the polymers during the reinforcement process.

In addition, organic carbon fiber/polyether ether compounds (CF/PEEK) and thermoplastic composites are being studied. Its mechanical strength and fatigue resistance are strong.

3.3. Joint prostheses

The biomaterial used in artificial joints is an emerging field. Prostheses with good stress and strain distribution the device in conjunction with the physiological response helps the user in the long term with promising effects and clinical success. Clinical experiments usually take time and biocompatibility is a major concern.

3.3.1. Total knee replacement

Biomaterials for prosthetic joints are still in their infancy as a field. When a prosthetic device is used in conjunction with the body's natural response, it can yield clinical success and promising benefits for the wearer over time. Clinical trials usually take a while, and one of the main problems with materials is biocompatibility.

Knee replacement is a laborious and often complicated procedure. The primary problem with carbon fiber-reinforced synthetic UHMWPE that existed previously was wear resistance, which resulted in a weak bond between them. A similar thing happened with UHMPWE and UHMWPE fibers, but in this case, we had increased stiffness and strength. Recent work by Utzschneider et al. investigated the wear resistance of cross-linked resin in various knee joints and found a significantly lower wear rate than UHMWPE.

Rahaman et al. provided a summary of the many properties of materials used in knee replacements, including:

- Excellent strength, modulus of elasticity, fracture toughness and fatigue resistance under pressure; body load varies from 3 kN for typical walking to 8 kN for running or stumbling).
- High corrosion resistance for in vivo biocompatibility and biological inertness.
- Excellent surface finish and high hardness to promote long-term wear resistance.
- Good surface moisture on the landing area.

3.3.2. Total hip replacement

America performs almost 150,000 procedures per year, making this kind of trade typical. It has a 93% success rate after 10 years and an 85% success rate within 15 years at the clinical level. However, the replacement exposes the bone to physiological stress. Chemically engineered fashion prostheses (Figure 180.1) add stiffness and strength in addition to style. To avoid discomfort caused by low-amplitude oscillatory motion, dentures should have the highest possible level of stress protection and the lowest possible stress stiffness. Additionally, a hip-style prosthesis made from a quality metal alloy may not be structurally compliant. Hip implants are inspected and optimized using finite element analysis and Srinivasan et al. to perform an in-depth analysis for the development of future implants. Computational techniques for stress analysis and performance analysis are useful in the design of ideal implants, including CF/PA12, CF/PA, and CF/HAP.

Fixation, specifically spheroidal fixation, is crucial for total hip replacements and emphasizes bone development cementation techniques in addition to design and properties.

3.4. Artificial tendons

The appearance and construction of composite nerve tendon prostheses are carefully considered when combining attributes such as structure, durability and biocompatibility. Hydrogels and polyesters are the most
Figure 180.1. Metal hip implant.

Source: Author.

common tendon substitutes. In the properties of the PHEMA matrix containing PET fibers are investigated. In addition, the fatigue resistance of a composite made of UHMWPE and ethylene butene polymer was investigated. The effects of polyose-containing polyester, which has potential use as a wound healing catalyst, were measured using an assay.

3.5. *Artificial cartilage*

The decisive component of healing is cartilage replacement with biomaterials. The fiber content and matrix composition of the material can be changed to obtain the desired properties of natural discs. Animal tissue and disc bones can be used in the development of biocomposites that are composed of UHMWPE with a three-dimensional structure coated with u-HA particles. As the tissue grows into the implant, its mechanical characteristics become part of it. This composite, tested in vivo, shows no signs of wear or infection; yet, massive failures of repair mechanisms have not yet been found.

4. Conclusion

The use of polymer composites in the field of biomedicine brings many opportunities. With the advancement of current technologies, these composites undergo constant modifications, leading to the addition of many mechanical properties that increase their biocompatibility. Binders can also be added to improve properties. Additionally, experiments are carried out to assess and enhance the outcomes. Taking into account the goals and constraints, the following information needs to be stated:

There is little reliability evidence supporting composite longevity compared to standard procedures.

There are more design variables because composites are more complex to construct than standard materials. Currently, there are no acceptable guidelines for evaluating the biocompatibility of composite materials. But as the science of biocomposites advances, we can hope for a better assisted living environment through the collaboration of materials scientists, bioengineers, chemists, and physicians.

181 Experimental study on ultra-high-performance fibre reinforced concrete beams

Swati Agrawal[a] and Madhu Sahu[b]

Assistant Professor, Department of Civil Engineering, Kalinga University, Raipur, India

Abstract: Engineers all around the world have been interested in since the mid-1990s, UHPFRC (Ultra-High-Performance Fiber-Reinforced Concrete) has been used because of its remarkable mechanical qualities, endurance, and fatigue resistance. The goal of the current study is to determine how well the hybrid technique works for verifying the current concrete model and analyzing the behavior of large-scale UHPFRC structural components. To do this, local UHPFRC was used to create four full-scale beams with varying cross-sections and spans, and conventional mixing and material methods were followed.. The beams were then tested under various stress scenarios until they failed. There were three distinct ways that beams under each technique were strengthened: a) extra reinforcement at the bottom side; b) extra reinforcement at the longitudinal side; and c) extra reinforcement at both the longitudinal and bottom side. Tests of flexural strength were performed to track distortion in the reinforcing steel. Test findings for beams under flexure revealed notable improvements brought about by strengthening procedures in terms of several behavioral characteristics like stiffness, failure load, and crack propagation. The most capacity improvement was seen in beams strengthened on both bottom and longitudinal sides, whereas the least amount of enhancement was seen in beams strengthened solely at the bottom. As part of the tensile retrofit, there were worries about UHPFRC's increasing use potentially leading to a loss of ductility.

Keywords: Structural applications, concrete reinforcement, durability testing, fiber volume fraction, microstructure analysis, fiber bonding, shrinkage and creep, sustainability in concrete

1. Introduction

An innovative cement composite material with great resilience to fracture, ductility, durability, and strength is called concrete reinforced with ultra-high performance fibers (UHPFRC) [1–3]. Studies on its structural performance and durability have shown encouraging findings thus far [14–18]. Reactive powder concrete with a fiber content high enough to induce strain hardening under stress and greater than 150 MPa of compressive strength is generally referred to as UHPFRC. Current studies have made an effort to develop internal UHPFRC blends that use readily available materials locally in an attempt to significantly boost UHPC use by reducing costs and simplifying manufacturing processes [4, 5].

The majority of research on UHPFRC that have been published concentrate on characterizing material characteristics [6–9]. A smaller number of studies examine the behavior of full-scale structural components, particularly when using mixes that are generated locally [10–12]. A notable example of a member-level research is that conducted by Graybeal [13], who looked at the possibility of building prestressed bridge girders using UHPFRC that were developed by Ductal [22]. According to reports, the girder fails as a result of the fiber pulling out. The flexural stress that the fibers carried at the time of fiber pull out was passed to the prestressing strands, increasing the tensile stresses in the strands and ultimately resulting in the girder collapsing and the prestressing strands breaking [20]. Yang et al. examined the effects of concrete installation techniques and the reinforcing ratio on UHPFRC beam flexural strength. [14, 15]. It was found that the final moment capabilities are highly dependent on the placement of UHPFRC inside the beams. Recently, Yoo et al. [16] investigated how utilizing various fibers affected the reinforced UHPFRC beams' flexural behavior. It was found that long steel fibers greatly enhanced ductility and the post-peak response, but had no effect on the ultimate moment capacity. It should be

noted that, despite the abundance of valuable research on the use of UHPFRC in RC beam strengthening and repair, none of them have specifically considered the effect that longitudinal side strengthening has on the beams' flexural strength. The aim of this study is to assess the effects of additional reinforcing an RC beam using UHPFRC, both alone (bottom side strengthening) and in combination (bottom side and two longitudinal sides strengthening).

2. Literature Review

Buttignol et al. 2017 evaluated the ultra-High-Performance Concrete material's mechanical characteristics and offers design suggestions. The material is available in many different combinations; Some of them require more complex mixing techniques and raise manufacturing costs because they include more than 1000 kg/m³ of binder [23]. UHPFRC can cause combination overheating and self-desiccation because to its short hydration time, lengthy inactive periods, and low hydration. The thick microstructure produced by the hydrated cement grains enhances mechanical qualities such as bond qualities, toughness, ductility, and high compressive strength capability [19]. To effectively benefit from UHPFRC, design codes should be validated and tensile constitutive laws should be constructed using bi-linear or tri-linear models [21]. High temperatures may exacerbate spalling triggering and reduce UHPC's mechanical characteristics.

Asmaa Said et al. 2022 examined the use of UHPFRC to reinforced concrete (RC) beam shear strengthening. The findings demonstrate that, in comparison to un-strengthened beams, Reinforced concrete (RC) beams ultimate stiffness, toughness, ductility, and shear strength are all increased by 1.49, 2.75, 3.37, and 4.77 times by UHPFRC. UHPFRC full casting is a more effective way to improve ultimate load, ductility, and toughness than UHPFRC laminates. Its behavior is more affected by strengthening the full beam than by strengthening only one third of it. A higher steel-to-fiber ratio enhances the UHPFRC combination's strength and ductility. The UHPFRC layer's initial ductility and stiffness rise with thickness.

Chen et al. 2021 investigated UHPC and high-strength concrete (HSC) beams both at room temperature and during exposure to temperatures ranging from 300 to 500°C. Two #4 rebars were used to provide longitudinal tensile reinforcement at the bottom and to reinforce the beams at an effective depth of 165 mm. The results showed that UHPC specimens had smaller deflection under load and were more stiff at the post-cracking stage than HSC specimens. Compared to HSC specimens, UHPC specimens have more ductility. The results of the investigation showed that after being heated, UHPC beams with hybrid polypropylene and steel fibers had improved flexural strength.

Lowering the moisture content of UHPC beams can also improve their ability to withstand spalling.

3. Material and Methods

3.1. *Reinforcing bars made of steel and concrete*

The ultimate tensile strengths of fu = 680 and 660 MPa and test yield stresses of fy = 590 MPa were recorded for the high-grade deformed bars with diameters of 10 mm and 8 mm, respectively. The same value, Es = 200 MPa, applied to both diameter bars.

A concrete cylinder measuring 75 by 150 mm was tested for compressive and split tensile strength. Tensile strength of split cylinder on average (3:16 MPa) additionally Average compressive strength of a cylinder over twenty-eight days (54 MPa) of the concrete were determined. The control beam specimens were under-reinforced before being strengthened using any of the two UHPFRC procedures, meaning that they were intended to fail in flexure.

3.2. *UHPFRC*

The components of the UHPFRC utilized in this investigation included steel fibers, water, superplasticizer, M-sand, Silica fume and Portland cement.

Two different steel fiber sizes, straight and hooked end fibers, were mixed in a 1:1 ratio. In contrast to the straight steel fibers' 0.2 mm length, 11 mm diameter, and 2250 MPa tensile strength, the hooked-end steel fibers measured 30 mm in length and 0.15 mm in diameter. Table 181.1 displays the UHPFRC mix

Table 181.1. Quantity of materials

Content	Combine ratio (kg/m³)
Cement	920
Silica fume	190
M-sand	1150

percentage. Table 181.2 shows the average values of UHPFRC's mechanical characteristics following samples' 28-day testing.

4. End Results and Talk

4.1. *Test of flexural strength*

The beam specimens underwent four points of loading during the flexure test. The longitudinal deformation of the concrete surrounding the midspan region was measured using concrete strain gauges, and the using differential transducers with linear variables, the midspan displacement was found.

The reinforcing steel in RC beams was monitored for deformation using strain gauges fastened to reinforcing bars.

When load rose, vertical cracks that began in the middle of the span and moved outward toward the supports were seen in CB Control, exhibiting the classic flexural fracture pattern. At the furthest points from the supports, inclined flexural-shear fractures began to form up until the failure load. The fractures were dispersed across the beam specimen's central 850 mm span. Regarding B1, at greater loads, the specimen

displays a combination of splitting flexural fractures and flexural cracks. Table 181.4 shows that the fracture load was more than double the control value, and most of the cracks were found in the beam's center span. A noticeable flexural fracture started to occur right at the mid-span of the beam and finally led to the failure crack. Among the specimens indicated above, B3 had the fewest number, distribution, and propagation of cracks. The center 350 mm of the beam specimen was where the majority of the fractures were located. This is because, in comparison to other specimens, B3 was larger and had the combined contribution of extra longitudinal and bottom reinforcement. As a result, B3 was able to perform better in terms of crack spread, stiffness, and ultimate load.

4.2. *Load deflection behavior*

It is generally known that the load-deflection behavior of CB is similar to that of the majority of ordinary, highly ductile under-reinforced beams in Table 181.3. As the load grew linearly up to the steel reinforcement yielding at a load level equivalent to 52 kN, there was a minor drop in stiffness upon breaking. After then, it displayed larger deformations up to failure, a significant drop in stiffness, and harderening than anticipated (all of which were compatible with the local steel's uniaxial tensile characteristics). The ultimate cause of failure was the concrete crushing under compression.

The behavior of Beams B1 and B2 was comparable to that of CB, with the exception that load rose quickly with increased stiffness until reinforcement yielded at 66 kN and 92 kN, respectively. As the load to yield rose, the maximum stresses in the concrete at the moment of steel yielding also increased in Table 181.5. This shows that as more reinforcement is applied, at steel yield, the neutral axis will decline. Once the yielding occurred,

Specimen ID	Movement at heavy loads (kN)	The residual displacement (mm)	Peak load (kN)	Enhancement of moment capacity (%)
CB	18.90	13.21	65	-
B1	16.26	11.62	82	14
B2	12.35	9.46	98	46
B3	5.01	3.20	128	90

Source: Author.

the UHPFRC softened and gradually ruptured in areas where the tensile strain exceeded 0.004, causing the load rise to decrease. Peak compressive stresses also show that the real failure occurred from crushing the concrete; in the case of the extra reinforcement at the bottom, this was normal concrete; in the case of the longitudinal reinforcement, it was either UHPFRC or regular concrete.

Comparable to steel bars, the UHPFRC laminate possesses tensile forces. Assuming a tensile strength of 6 MPa, a bottom laminate with a thickness of 25 mm can rupture with a force of 25 kN. This yield force of 95 kN in the two steel bars compares favorably with this. The behavior of the initially under-reinforced section may effectively be changed to that of an over-reinforced section by adding tension effective UHPFRC, as shown by the comparison of these numbers. After yielding at strain values near 0.002, the beam steel continues to harden and provide greater tensile force as the tension side stresses rise and the UHPFRC absorbs tensile energy. The UHPFRC and the beam steel cooperate until the strains approach 0.004, at which point the UHPFRC starts to break and release its tensile contribution. A lower neutral axis position with increased tension effective UHPFRC allows normal concrete compressive strain to approach crushing strain value before significant steel post-yielding, which causes an undesirable brittle failure. This is because the ductility index is dependent on the location of the neutral axis.

In the instance of B3, the beam exhibited a greater increase in load and decreased deformation until the reinforcement yielded, which happens at a higher load of 120 kN. In contrast to CB, B1, and B2, there was a much less ductile failure as the load climbed to 131 kN following the yield in a softening mode, followed by a sudden drop in load and a modest decrease in stiffness. The brittle character of B3's failure may be ascribed to the UHPFRC's crushing at strain values between 0.0017 and 0.0023. Even though every beam broke down through crushing, the reason for this configuration's lack of ductility is that the UHPFRC compressive strain was about 0.0017 at the moment the steel yielded. Out of all the tested beams, this one had the greatest recorded concrete strain. This suggests that the neutral axis has lowered, as it does in conventional reinforced concrete beams, and that there has also been a decrease in ductility. It is challenging to transfer compression in a steady way after crushing starts because of the concrete's lower compressive strength and closer crushing strain to the UHPFRC.

5. Conclusion

The experimental study of the flexure behavior of UHPFRC beams reinforced with traditional steel bar reinforcement is presented in this work. Variations in interface preparation techniques did not appreciably affect the flexural testing results of the reinforced beams. When compared to control beam specimens, UHPFRC strengthening greatly increased the stiffness of concrete beams under service conditions, minimizing deformations under applied loads. In addition, it dispersed cracks, delayed the propagation of fractures, and raised the cracking stress. This might be explained by the robust tensile strength and tensile plastic stretching that are characteristic of UHPFRC. Furthermore, the addition of UHPFRC to the sides and bottom of the object increases its moment of inertia, which may potentially be the cause of this. Lastly, the fact that the fracture propagation is less near the support zone indicates that the addition of reinforcement has improved the shear strength.

182 Optimizing CNN architecture for facial emotion recognition: Experimental evaluation and parameter tuning

Uruj Jaleel[1,a] and Mohit Shrivastav[2,b]

[1]Associate Professor, Department of CS and IT, Kalinga University, Raipur, India
[2]Research Scholar, Department of CS and IT, Kalinga University, Raipur, India

Abstract: Facial emotion recognition plays a pivotal role in human-computer interaction and affective computing systems. In this study, we propose a novel CNN-LSTM framework designed to predict facial emotions by combining spatial feature extraction with temporal analysis. The framework begins with robust face detection and extraction techniques to isolate the facial region, ensuring focused analysis on critical facial components. Following extraction, extensive pre-processing techniques enhance image quality and feature visibility, crucial for accurate emotion interpretation. Histogram equalization standardizes intensity levels, improving contrast and clarity of facial features essential for subsequent analysis. These processed images are then fed into a CNN architecture comprising multiple convolutional layers that extract intricate spatial features from the facial data. The CNN-generated feature maps undergo further analysis by an LSTM component, which captures temporal dependencies and patterns across sequential data points. This dual approach enables our framework to effectively discern subtle changes and nuances in facial expressions over time, enhancing emotion prediction accuracy. Evaluation of different CNN layer configurations revealed that a model with five layers achieved optimal accuracy, balancing computational efficiency with performance gains. Our experiments, conducted on merged datasets—Japanese Female Facial Expression and Karolinska Directed Emotional Faces—underscored the framework's robustness and generalization capabilities across diverse emotional expressions. In conclusion, the proposed CNN-LSTM framework offers a comprehensive solution for facial emotion prediction, leveraging spatial and temporal information effectively. The findings highlight the significance of architectural choices in optimizing emotion recognition systems, with implications for applications in interactive technologies and psychological research. Future research could explore enhancements for real-time performance and scalability in varied operational contexts.

Keywords: Facial emotion recognition, CNN-LSTM framework, convolutional neural network, face detection, emotion prediction, human-computer interaction, affective computing, deep learning, dataset augmentation, neural network architecture

1. Introduction

Human facial expressions are important markers of emotions, involvement, and interaction that are fundamental in interpersonal communication. The development of models that can precisely identify and understand these emotions is becoming more and more important as artificial intelligence (AI) and machine learning (ML) advance so quickly. Enhancing human-machine interactions is the goal of this development. With the goal of giving machines the capacity to recognize and understand human emotions from facial clues, the study of facial emotion detection systems

has become increasingly promising. Face detection and emotion recognition are the two main parts of these systems, usually [27]. Face detection recognizes faces in pictures or videos, while emotion recognition examines these faces to identify the underlying emotions.

Advances in computer vision in recent times have prompted a great deal of study on face detection techniques. Neural networks were first applied to face detection by pioneers like Vaillant et al., who used methods like convolutional neural networks (CNNs) and sliding window techniques. Linked neural networks have been used in later methods to improve facial identification systems' accuracy. The development of

these algorithms has been greatly aided by standardized evaluation frameworks like the Face Detection Database and Benchmark, PASCAL FACE, and Wilder Face-Face Detection Benchmark. These benchmarks make it easier to compare and rigorously evaluate multiple face detection models, which improves the ability of machines to recognize and react to human emotions in a variety of applications [26].

Face detection algorithms can be classified into distinct categories based on their methodologies and characteristics, each contributing uniquely to the field's advancement.

Cascade-Based Algorithms such as those developed by Viola and Jones and further refined by Lienhart and Maydt, utilize a cascading series of classifiers to progressively refine the face detection process. This method improves both accuracy and efficiency by employing multiple classifiers in a sequential manner. The preprocessing steps usually involve variance normalization and the calculation of integral images to facilitate efficient feature evaluation. Key performance metrics for these algorithms include the detection rate, false positive rate, and ROC (Receiver Operating Characteristic) curves.

Part-Based Algorithms tackle face identification by segmenting the problem into identifying distinct facial characteristics, such as the mouth, nose, and eyes. Belhumeur et al. and Yang et al.'s contributions serve as excellent examples of this method. To precisely identify the full facial region, these algorithms examine each of these elements separately and combine their findings. Preprocessing usually entails creating a three-dimensional base from pictures taken in different lighting scenarios. Performance metrics use datasets from organizations such as the Yale Center for Computational Vision and the Harvard Robotics Lab to evaluate recognition mistake rates under various lighting and facial expression conditions.

According to studies by Yan and Kassim and Wu et al., channel feature-based algorithms use feature maps or different color channels to detect patterns in faces and set them out from the backdrop. Real photo acquisition with registration is combined with artificial blurring of images with different blur widths and noise levels as part of the preprocessing procedures. Normalized Root Mean Square Error, convergence analysis, comparisons with other approaches, visual inspections of reconstructed images, and approximated Point Spread Functions are some of the evaluation measures.

Facial expression recognition has received a lot of attention in addition to developments in face detection. For the purpose of identifying facial emotions, researchers have investigated neural network-based Hidden Markov Model techniques and created systems that make use of Facial Action Coding. For facial cue-based emotional interpretation, facial emotion prediction—which usually comes after face detection—is essential. The significance of this field is demonstrated by recent works like "Emotion Recognition Using a Transformer-based Architecture" and "Learning Dynamic Affective Contexts for Facial Emotion Recognition". Research projects such as "Facial Expression Recognition using Spatiotemporal Attention Mechanism" and "Efficient Facial Emotion Recognition using Siamese Neural Networks" show that facial emotion prediction accuracy and efficiency are constantly improving. Notwithstanding these developments, there are still large research gaps in this field.

Numerous studies highlight challenges stemming from extraneous and misleading features in face detection methods, complicating training processes and diminishing accuracy. These issues pose practical hurdles, particularly in real-world applications, delaying the deployment of face detection algorithms. Therefore, there is a critical need to develop frameworks that efficiently eliminate irrelevant background information, focusing exclusively on essential facial features to ensure accurate detection across diverse fields.

Despite significant advancements driven by extensive datasets, sophisticated models, and ongoing benchmarking efforts, the persistence of unnecessary features continues to disrupt training and reduce accuracy levels. Addressing these complexities necessitates frameworks that prioritize the filtration of irrelevant background data, simplifying model architectures for seamless deployment across practical domains.

To tackle these challenges effectively, we propose a robust deep learning framework specifically designed for precise classification of seven primary facial expressions: happiness, surprise, disgust, neutrality, fear, sadness, and anger. Our approach prioritizes simplicity by eliminating irrelevant features, enhancing the applicability of the model in real-world scenarios. Central to our solution is a specialized CNN-LSTM architecture engineered to minimize unnecessary features during training. This involves rigorous steps such as face detection, precise estimation of facial regions, and comprehensive preprocessing to optimize feature recognition. Our method optimally configures the CNN-LSTM model to accurately interpret facial expressions, achieving a notable accuracy of 78.1% through rigorous training on challenging datasets, surpassing baseline model performances.

Building on the success of our model, we have developed a practical application for real-time facial emotion detection in both videos and images. Leveraging our trained model, this application delivers precise emotion recognition for diverse practical applications. Our contributions in facial emotion prediction encompass:

1. Efficient Emotion Prediction System: Our CNN-LSTM framework predicts facial emotions by

assigning probability scores to each emotion class, ensuring precise identification of emotions conveyed in facial expressions.

2. Enhanced Preprocessing Techniques: Recognizing the importance of data quality in deep learning, our system integrates diverse preprocessing steps tailored to each image. This enhances prediction accuracy by enabling the neural network to effectively identify relevant facial features.

3. Real-Time Emotion Classification Interface: To enhance usability, we developed a graphical user interface (GUI) for real-time emotion classification. This interface enables users to obtain emotion predictions promptly from live videos and static images.

The format of this article is as follows: In Section 2, we provide further details on our suggested emotion recognition system, including the CNN-LSTM architecture and how it assigns probability to different classes of facial expressions. In Section 3, the effectiveness of the system is assessed. The datasets utilized for training and testing are discussed, and experimental findings proving the accuracy of the model are presented. The GUI for real-time emotion classification is introduced in Section 4, making it easier for users to engage with the system. In summary, our contributions to the advancement of facial emotion prediction systems are summarized in Section 5, which brings the article to a close.

2. Literature Review

The field of remote sensing activities like object detection and scene recognition has greatly benefited from the development of deep learning algorithms, especially in the area of picture recognition. The extensive use of remote sensing equipment has resulted in fragmented data quantities held by numerous entities, including remote sensing firms, and decentralized data distribution. To enhance model efficacy while ensuring data security, federated learning has emerged as a prominent approach in remote sensing [13]. However, federated learning encounters substantial security challenges, including adversarial attacks, backdoor attacks, and particularly, membership inference attacks. These threats exploit the model's parameters, posing significant security risks. Despite extensive research on traditional federated learning (FL) applications in addressing these attacks, there remains a gap in addressing them within the context of remote sensing scenarios. Therefore, we propose the LDP-Fed framework to mitigate membership inference attacks in federated learning specifically tailored for remote sensing. This article will explore relevant literature across three domains: the integration of machine learning in remote sensing, membership inference attacks, and strategies to defend against such threats.

2.1. Machine learning in remote sensing

The use of sophisticated machine learning models for the classification of remote sensing picture data has been thoroughly investigated by researchers [14]. In order to develop invariant decision functions, Gei et al. [15] proposed the Virtual Support Vector Machine with Self-Learning (VSVM-SL) as a solution to the problem of effectively classifying sparse remote sensing data. Meanwhile, Wang et al. [16] showed that the Random Forest (RF) approach outperformed SVM for land-cover datasets, emphasizing the algorithm's stability and effectiveness in the categorization of remote sensing images. Convolutional Neural Networks (CNNs) are now the most widely used method for classifying remote sensing images since the development of deep learning. Zhang and associates [17] introduced CNN-CapsNet, enhancing scene classification by leveraging pretrained CNNs for feature extraction and CapsNet for classifying intermediate features. Li et al. [18] applied CNNs to multi-target scene classification, proposing MLRSSC-CNN-GNN to integrate CNN-derived features with spatial-topological relationships using a graph attention network. Tang et al. [19] developed ACNet, a CNN model emphasizing local image features to improve classification accuracy. Chen et al. [20] addressed few-shot classification challenges with CNSPN, integrating semantic information from image class names.

As deep neural networks continue to advance in remote sensing image recognition, security concerns have become paramount, encompassing vulnerabilities such as backdoor attacks [21] and adversarial attacks [22]. To further enhance remote sensing image classification, we propose the integration of CNN and LSTM architectures. The CNN component extracts spatial features efficiently from remote sensing images, while the LSTM component captures temporal dependencies, enhancing overall classification performance and resilience against security threats. This article focuses on integrating CNN-LSTM architectures for remote sensing image classification and introduces advanced federated learning frameworks to mitigate security risks. Specifically, we introduce the LDP-Fed framework, designed to counter membership inference attacks and bolster the security and practical application of federated learning in remote sensing.

2.2. Membership inference attack

Membership inference attacks (MIAs) can be categorized into white-box and black-box MIAs based on the information the attacker has about the target model.

2.3. *Black-Box membership inference attacks*

Shokri et al. [23] pioneered research on Membership Inference Attacks (MIAs) targeting classification models. They developed an attack model that exploits discrepancies in predictions between trained and untrained data to infer membership in the training dataset. In a black-box scenario, attackers must train multiple shadow models to approximate the target model, which significantly affects the efficacy of the attack. Their findings highlighted a strong correlation between overfitting and susceptibility to MIAs, emphasizing the role of regularization techniques like L2 regularization and dropout in mitigating these attacks.

Yeom et al. [24] proposed an alternative approach to MIAs by quantitatively analyzing differences in loss between training and testing datasets, simplifying the process of identifying membership. Salem et al. [25] contributed by introducing a lightweight MIA strategy aimed at reducing the number of shadow models required. These methods rely on leveraging black-box characteristics of the target model, such as its predictive outputs, to execute the inference attack.

2.4. *White-Box membership inference attacks*

In contrast, Nasr et al. [26] introduced a comprehensive white-box framework for Membership Inference Attacks (MIAs), assuming attackers possess some knowledge about the training dataset. Their approach involves constructing an attack model's training dataset using forward and backward propagation to gather comprehensive model outputs, including gradients, neuron activations, and losses at various data points. They augment this dataset with a binary indicator to denote whether each data point was used in training the target model. This method outperforms black-box approaches by leveraging detailed internal model information.

Nasr et al. [27] further emphasized that MIAs are particularly potent in federated learning (FL) settings due to the frequent exchange of model updates between the central server and participating clients, which provides attackers with abundant information to launch effective inference attacks.

2.5. *CNN-LSTM integration for MIAs*

Integrating CNN and LSTM architectures can refine and amplify membership inference attacks. The CNN component excels at extracting spatial features from model outputs, while the LSTM component specializes in capturing temporal dependencies across different training epochs or communication rounds in federated learning. This amalgamation enhances the ability to discern between trained and untrained data points, thereby enhancing the precision and effectiveness of membership inference attacks.

This article explores the application of CNN-LSTM models to enhance the efficacy of MIAs in both black-box and white-box scenarios. We delve into the security implications of these attacks, particularly within federated learning environments where heightened data communication increases vulnerability. Our proposed methodologies aim to bolster the security of machine learning models against membership inference attacks by leveraging sophisticated deep learning architectures.

2.6. *Défense mechanism against membership inference attack*

Due to the effectiveness of membership inference attacks (MIAs) against different deep neural network (DNN) models, researchers have created a number of defense mechanisms. Four general categories can be used to group these solutions: knowledge distillation, regularization approaches, differential privacy, and confidence score masking. For CNN-LSTM models, these defense mechanisms can be integrated to enhance security against MIAs. Confidence score masking can be applied to the outputs of the CNN component, while regularization techniques can be used throughout the CNN-LSTM architecture to prevent overfitting. Knowledge distillation can train the LSTM component with softened outputs from a more complex model, and differential privacy can be incorporated during the training of both CNN and LSTM layers. Combining these strategies can effectively mitigate the risks posed by MIAs, even in complex sequential data scenarios handled by CNN-LSTM models.

3. Proposed Methodology

Figure 182.1 illustrates the schematic representation of our proposed CNN-LSTM framework designed for facial emotion prediction. Initially, the system identifies and isolates the facial region from the background within the image. This step is critical for focusing the subsequent analysis exclusively on the facial features of interest. Following extraction, the facial image undergoes thorough pre-processing. This stage prepares the input data by employing various techniques to optimize image quality and enhance the visibility of relevant facial features. Effective pre-processing ensures that the neural network can accurately interpret and analyse the emotional cues present in the image.

The pre-processed facial image is inputted into the CNN module of our framework. The CNN employs multiple layers of convolution, pooling, and activation functions to extract spatial features that are pertinent to emotional expression. This process results in a collection of feature maps that encapsulate crucial details of the facial structure and expression. The feature maps generated by the CNN are subsequently fed into the LSTM component. Here, the LSTM conducts temporal analysis across different frames or sequential data points. By capturing temporal dependencies and patterns in facial expressions over time, the LSTM enhances the framework's capability to interpret dynamic emotional states accurately. The output from the LSTM module comprises probability scores assigned to each predefined emotion class—such as anger, disgust, fear, happiness, sadness, surprise, and neutrality. These probabilities indicate the model's confidence in predicting each emotion based on the extracted facial features and their temporal dynamics.

Finally, the emotion class with the highest probability score is identified as the predicted emotion for the input facial image. This classification step involves assigning the image to the emotion category that the model deems most likely. In summary, our CNN-LSTM framework integrates spatial feature extraction with temporal analysis to deliver a robust system for predicting facial emotions. Each phase of the framework is detailed further in subsequent sections of our study, offering a comprehensive overview of its functionality and performance characteristics.

3.1. Face detection

Face identification is an important first step in our CNN-LSTM system for facial emotion prediction. Numerous methods, such as deep learning models, Haar cascades, and Histogram of Oriented Gradients (HOG) with Support Vector Machine (SVM), have been developed for face detection. We use an approach for our system that is well known for its effectiveness and real-time capabilities. 68 (x, y) positions on the detected face that correspond to important facial landmarks are accurately identified by this method. These turning points are essential for further examination. To train the face detection component, we utilize a
Figure 182.1. Proposed architecture.

Source: Author.

labelled dataset containing facial points annotated on images. Each (x, y) coordinate meticulously maps to specific facial regions. Based on the brightness of the pixels in the image, the program uses a regression tree model to predict these facial landmarks. This method's remarkable speed and real-time performance are attributed to the exclusion of conventional feature extraction techniques, which also maintains accuracy and quality. The CNN part of our approach uses the 68 facial landmarks as inputs after face detection. This CNN extracts spatial features from these key points. Subsequently, these features undergo analysis by the LSTM component, which captures temporal dynamics in facial expressions. By combining CNN for spatial detail extraction and LSTM for temporal pattern recognition, our system achieves robust and precise facial emotion prediction. Subsequent sections of our framework delve deeper into the processing and analysis of these detected features, providing a comprehensive overview of how the system operates and its effectiveness in emotion recognition.

3.2. Face extraction

After successfully detecting faces using our CNN-LSTM framework in input images, the next crucial task is accurately extracting the detected facial region from the original image while effectively eliminating the surrounding background. This step is pivotal in isolating the specific area of interest—the face—ensuring that subsequent facial analysis and emotion recognition are precise and targeted. Our approach can focus just on important facial features—like the mouth, nose, eyes, and eyebrows—by isolating the facial region. These features are essential for predicting facial emotions. It is ensured that only pertinent facial features are taken into account for additional processing by eliminating the backdrop.

This extraction procedure is an essential pre-processing method that greatly increases the effectiveness and precision of our algorithms for recognising face emotions. Our next research may use facial area isolation to pinpoint and prioritize the essential elements that convey emotional expressions, leading to more accurate and consistent predictions of human emotions. This face extraction process is fundamental because it allows our framework to precisely analyze and anticipate facial expressions by concentrating just on the essential facial features.

3.3. Preprocessing

Once the facial mask is applied to locate and extract the facial area from the original images, as illustrated in Figure 182.1, this method utilizes the mask as a filter: white pixels designate the facial area, while black

pixels indicate the related. We are able to separate the face area from the background by applying this mask to the original photos. The resulting images are optimized for tasks linked to face emotion identification and further analysis since they only include the most important facial features.

This extraction approach makes sure that any further processing focuses only on important facial features, which makes it easier to forecast human emotions with accuracy and dependability. In our facial emotion prediction system, the CNN-LSTM architecture uses the extracted face images as input data. These extracted face photos go through a series of pre-processing processes to make sure the CNN-LSTM model receives well-prepared data. These actions are essential for improving the model's ability to pick up relevant characteristics and make accurate predictions.

First, the cropped face photos are subjected to histogram equalization as part of the pre-processing procedure. By standardizing intensity levels and boosting contrast, this approach makes face features more visible and distinct. This preparatory step optimizes the input data for subsequent stages of analysis within our CNN-LSTM framework, ensuring robust performance in facial emotion recognition.

3.4. CNN-LSTM architecture

Our CNN-LSTM framework's suggested architecture for facial emotion prediction is built with layers intended to efficiently recognize and categorize emotions from input face images. The distinctive components of this model are its five convolutional layers, one max pooling layer, two average pooling layers, and three dense layers.

This setup was designed with care to maximize feature extraction and classification, strengthening the system's capacity to identify a wide range of facial emotions. We include a 20% dropout rate in the dense layers for regularization to combat overfitting and enhance generalization. The input layer's dimensions are 80 x 100, which corresponds to the size of the face photos that our system uses.

Using the ReLU activation function, the first convolutional layer starts with 64 filters of size (5, 5). After processing the incoming images, this layer generates an output size of (76, 96, 64). The dimensions are then reduced to (36, 46, 64) via a max pooling layer with a pooling size of (5, 5) and strides of (2, 2). The architecture then consists of two convolutional layers that are placed one after the other. Each of these layers uses 64 filters with a kernel size of (3, 3) and an activation function of ReLU. These layers further extract intricate features from the input, enhancing the model's ability to discern subtle facial expressions and nuances related to different emotions.

In our CNN-LSTM framework's suggested architecture for facial emotion prediction is built with certain layers that are ideal for identifying and categorizing emotions from input face images. Five convolutional layers, one max pooling layer, two average pooling layers, and three dense layers are some of the main parts of this model. These components are strategically selected to maximize feature extraction and classification accuracy, thereby enhancing the system's capability for robust facial emotion recognition. To mitigate overfitting and enhance generalization, we integrate a dropout rate of 20% within the dense layers for regularization purposes. The input layer is tailored to accommodate images sized at 80 x 100 pixels, aligning with the dimensions of the facial images utilized in our system.

Using the Rectified Linear Unit (ReLU) activation function, the first convolutional layer begins with 64 filters of size (5, 5). Once the incoming photos are processed, this layer generates an output size of (76, 96, 64). The dimensions are then reduced to (36, 46, 64) via a max pooling layer with a pooling size of (5, 5) and strides of (2, 2). The architecture then consists of two convolutional layers that are placed one after the other. Each of these layers uses 64 filters with a kernel size of (3, 3) and ReLU activation. These layers further extract intricate features from the input, enhancing the model's ability to discern subtle facial expressions and nuances associated with different emotions.

The second convolutional layer plays a crucial role in our CNN-LSTM architecture for face emotion prediction, yielding an output size of (32, 42, 64). By taking this step, the model's ability to extract pertinent characteristics from the input data is much improved, which in turn improves the recognition of patterns in facial expressions. The output is then run through an average pooling layer with (2, 2) strides and a pool size of (3, 3), yielding an output size of (15, 20, 64). The resultant processed output is then sent through two more convolutional layers, each of which uses a kernel size of (3, 3) with ReLU activation and 128 filters. This results in an output size of (11, 16, 128). Next, a second average pooling layer with a configuration comparable to the first one brings the dimensions down to (5, 7, 128).

The output is then flattened into a 4480-size one-dimensional vector, which is then used as the input for three completely connected dense layers, each with 1024 filters. For every dense layer, a dropout rate of 0.2 is implemented in order to improve resilience and reduce overfitting. Using the SoftMax activation function, the last dense layer generates an output size of 7. The probability of each emotion class—anger, disgust, fear, happiness, sadness, surprise, and neutrality—are represented by these seven values. Ensuring precise

and dependable emotion recognition, the emotion class with the highest probability is the model's forecast for the provided face expression.

ReLU activation is purposefully used in the convolutional layers because it helps with vanishing gradients and encourages sparse representation—two things that are beneficial for deep learning applications. Our CNN-LSTM model is based on this architecture, which is shown in Figure 182.2 and allows for accurate and effective facial emotion prediction.

4. Result and Discussion

Within the CNN-LSTM framework's evaluation part, we first give a comprehensive overview of the dataset that we used in our research before delving deeply into the performance that our suggested systems have shown. We offer comprehensive insights into how the dataset was curated and prepared for training and testing purposes. Subsequently, we meticulously analyse and present the results of our CNN-LSTM model's performance in predicting facial emotions. This includes discussing metrics such as accuracy, precision, recall, and F1-score to assess the effectiveness and robustness of our approach in recognizing and classifying different emotional states from facial expressions.

4.1. Dataset

In this work, we improved our facial emotion identification system by integrating two different datasets. The 213 grayscale photos in the Japanese Female Facial Expression dataset were taken at a resolution of 256 by 256 pixels and include 10 models. On the other hand, 4900 grayscale pictures with a size of 572 × 762 pixels, taken from 70 models, are included in the Karolinska Directed Emotional Faces collection. The models were not wearing spectacles, earrings, or makeup, and all photos were shot in uniform lighting. Every model was imaged using a uniform procedure that included taking pictures from five different angles: frontal, full right, half left, half right, and entire left. The positions of the mouth and eyes were consistently fixed on a grid to ensure uniform alignment of facial features. Images were cropped to specified resolutions to maintain dataset uniformity.

The models represented in both datasets were aged between 20 and 30 years, ensuring consistency for emotion analysis. The combined dataset encompasses seven facial expressions: Anger, Disgust, Fear, Happiness, Sadness, Surprise, and Neutral. Each expression was assigned a numeric label (0–6) to facilitate systematic processing and classification within our system. While popular, datasets like JAFFE and KDEF have limitations in diversity across age, ethnicity, gender, and cultural backgrounds, which could impact model performance in real-world applications.

To overcome these limitations, we merged and organized both datasets based on emotion labels. Extensive preprocessing and augmentation techniques were applied, including rotation, brightness adjustment, geometric transformations, and noise injection. These methods aimed to bolster model robustness and enhance generalization, particularly in recognizing facial emotions under varying conditions. The training dataset comprised 14,200 images, with approximately 11% reserved for testing, totalling 1,580 images. This partitioning strategy enabled effective model training while rigorously evaluating performance on unseen data.

During preprocessing, images lacking detectable faces were excluded to prioritize accurate emotion recognition from well-defined facial regions. We maintained dataset balance by ensuring each emotion class had an equitable number of samples, ensuring the model could learn diverse facial expressions and generalize effectively during testing. Through the integration and processing of these datasets, we curated a comprehensive dataset tailored for training and evaluating our facial emotion recognition system, ensuring its suitability for real-world deployment.

To find the best architecture and parameters for our CNN model in facial emotion identification, we ran a number of trials during our evaluation phase. After adjusting the hyperparameters initially, we used Stochastic Gradient Descent as the optimizer and determined a learning rate of 0.01 and a batch size of 100. Our criteria for convergence was to attain a constant level of model accuracy over a period of twenty to thirty epochs.

First, we experimented with different CNN layer configurations (1–8) in order to find the best setting for accuracy. After a lot of testing, we discovered that five CNN layers produced the best accuracy of 70.2%. Longer computation times without corresponding increases in accuracy were the outcome of adding
Figure 182.2. Emotion distribution.

Source: Author.

more layers. This optimal configuration underwent rigorous testing in subsequent experiments to refine and enhance the system's performance.

Figure 182.3 illustrates the trend of accuracy with varying CNN layers, highlighting the peak performance achieved with five layers. This outcome guided our decision to adopt this configuration for its balance between computational efficiency and accuracy in facial emotion recognition.

In this study, we conducted a series of experiments to investigate the influence of increasing the number of convolutional layers on the performance of our CNN-LSTM model for facial emotion recognition. Specifically, we analysed the training accuracy across different epochs for configurations with 1 to 8 convolutional layers. The graph plotted (Figure 182.4) illustrates these accuracy trends, providing insights into the optimal architectural choices for our system.

The number of epochs, or total iterations through the training dataset, is shown on the x-axis. The y-axis indicates the training accuracy, reflecting the proportion of correctly classified instances during training. Each line in the graph corresponds to a different CNN layer configuration, ranging from 1 to 8 layers. The color-coded lines help in distinguishing the accuracy trends for each configuration.

The training accuracy vs. number of epochs graph for different CNN layer configurations provides valuable insights into the architecture selection for facial emotion recognition. The 5-layer configuration

Figure 182.3. Accuracy vs number of layers.

Source: Author.

Figure 182.4. Training accuracy vs number of epochs for different CNN layer.

Source: Author.

emerged as the optimal choice, balancing complexity, and performance. Adding more layers beyond this point leads to diminishing returns, while fewer layers fail to capture necessary features. These findings guide the architectural design of our CNN-LSTM model, ensuring effective and efficient emotion recognition from facial images.

5. Conclusion

In this study, we proposed a robust CNN-LSTM framework for facial emotion prediction, integrating spatial feature extraction and temporal analysis to enhance accuracy. The framework begins with face detection and extraction, isolating the facial region from images to focus exclusively on essential facial components. This step ensures that subsequent analyses are precise and relevant to emotion recognition. Following face extraction, comprehensive preprocessing techniques are applied to enhance image quality and feature visibility. Histogram equalization standardizes intensity levels, improving contrast and clarity of facial features crucial for emotion interpretation. These prepared images are then fed into the CNN component, comprising multiple convolutional layers that extract spatial features from the facial data.

The CNN-generated feature maps are subsequently analysed by the LSTM component, which captures temporal dependencies and patterns across sequential data points. This dual approach of CNN for spatial feature extraction and LSTM for temporal analysis enables our framework to effectively discern nuanced emotional expressions over time. The final stage involves emotion classification, where the LSTM output produces probability scores for each emotion class—anger, disgust, fear, happiness, sadness, surprise, and neutrality. The highest probability determines the predicted emotion, ensuring accurate and reliable emotion recognition. Through experimentation, we optimized our CNN-LSTM architecture by evaluating different configurations of CNN layers. We found that a model with five CNN layers achieved peak accuracy, demonstrating a balance between computational efficiency and performance. Increasing the number of layers beyond five yielded diminishing returns, while fewer layers compromised the model's ability to capture complex facial expressions. Our evaluation on merged datasets—Japanese Female Facial Expression and Karolinska Directed Emotional Faces—showcased the framework's robustness and generalization capabilities. By curating a diverse dataset and employing rigorous data augmentation techniques, we ensured that our model can accurately recognize facial emotions under varied conditions.

183 Computational screening of the lead compounds for obesity by targeting human FTO mutant E234P with various ligand library using *in-silico* approach

Nithya N.[1,a] and Anbarasu K.[2]

[1]Research Scholar, Department of Bioinformatics, SIMATS School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Project Guide, Department of Bioinformatics, SIMATS School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The current study intends to investigate the expected interactions of the obesity-related FTO protein mutant E234P and agonists of non-flavonoid polyphenols and anthraquinones to determine the best novel lead organic compound of obesity illness using computational methods. Materials and Methods. We succeeded to obtain the RCSB PDB structure for the FTO protein for the current investigation. A list of ligands was assembled from PubChem to assess the stability of targets about one another. In AutoDock VINA, molecular docking was done with PyRx, while analysis was done with LigPlus. According to Lipinksi's Rule of Five, each compound was evaluated using the MOLINSPIRATION programme. Results. The best ligand that exhibits an impact on suppressing the obesity-causing protein FTO is discovered to be chrysophanol based on the least binding affinity and hydrogen bonds. Conclusion. As a result, we investigated the interactions of the 11 phenolic non-flavonoids and anthraquinones with the protein. We used the binding energy as a criterion to select the best molecule from a collection of ligands. The hydrogen bonding and hydrophobic interactions were also visualized to choose the optimal ligand. A naturally occurring anthraquinone called Chrysophanol was found to be the best lead compound, helpful in preventing obesity, and supportive of people living healthy lives.

Keywords: Obesity, FTO, mutation, novel in-silico method, PyRx, LigPlus, diseases, healthy lives

1. Introduction

As the pharmaceutical sector is evolving towards a research-based strategy, modern medicinal chemistry techniques like molecular modeling and molecular docking have developed into useful tools for studying structure-activity correlations (SARs). The preferred orientation of the bound molecules can be used to predict the intensity and stability of energy profiles in complexes. Molecular docking helps in the discovery of novel lead compounds that could be utilized to develop a new clinically useful treatment for conditions like obesity. Small molecules, such as ligands, can be expected to bind to proteins, carbohydrates, and nucleic acids as a result of molecular docking.

An excessive buildup of body fat caused by obesity, a complicated illness, makes it difficult to live a healthy lifestyle. Cancer, diabetes, hypertension, cardiovascular and cerebrovascular disease, sexual and hormonal disorders, and others are just a few of the numerous and hazardous comorbidities connected to it [7]. Obesity is greatly impacted by eating, sleeping, and exercise habits as well as genetic factors including mutation (E234P) in the fat mass and obesity-associated protein (FTO), which can all lead to weight gain [19]. FTO regulates thermogenesis, adipocyte differentiation, and body fat mass [5].

Over the past few years, there have been more than 65000 research and review articles about obesity published in PubMed studies. Few of them talked about computational techniques for preventing the protein FTO [10]. Resveratrol [3], Orlistat [1], and Rhein [21] are some examples of ligands that have been used to treat obesity. In this study's molecular docking, anthraquinones and polyphenol non-flavonoids were employed. In addition to having anti-inflammatory properties, polyphenols and non-flavonoids aid in digestion by promoting the development of good bacteria in the stomach while inhibiting the development of unfavourable bacteria for long-term health. They are used to treat cancer, multiple sclerosis, arthritis, and constipation since anthraquinone derivatives have a long history of use as laxatives, antimicrobials, and anti-inflammatory drugs [18]. The majority of studies on the treatment of obesity are built on in vivo and in vitro techniques. The in-silico approach was selected for this study because it produced reliable predictions of chemical interactions. After gathering the protein information from UniProt, we used molecular docking techniques with ligands we purchased from PubChem to forecast the proteins' preferred binding models. To visualize compound interactions in silico, we used the Autodock vina method together with virtual screening tools like PyRx and LigPlus. Lipinski's rule of five were examined to predict the compound's druggability.

2. Materials and Methods

The experiments for the current research was conducted in the laboratory of Bioinformatics in Saveetha School of Engineering, SIMATS, Chennai. The analyses performed for the current study were carried out utilising bioinformatics tools such as LigPlus [23], Swiss pdb viewer [9], ICM pocket finder and PyRx [15]. The FTO protein's sequence, function, and 3D structure were all obtained from Swiss PDB and Uniprot, two publicly available databases of protein sequences and functions. A database called PubChem contains the 2D and 3D chemical structures of chemicals as well as details about their biological activity [14]. With its help, we were able to produce polyphenol non-flavonoids and anthraquinones for docking.

There is a Swiss model interface made possible to analyze protein structures by a user-friendly application called Swiss-PdbViewer [8]. The application offered a mutation tool that is used to cause the mutation E234P in FTO protein.

In UCSF Chimera, molecular structures and related data can be visualized and analyzed interactively [2]. Imported a protein pdb molecule in Chimera and add H atoms, then charge it for structure retainment. After that, minimize the structure in structure editing.

By optimizing the energy of a molecule, we can find the best conformation for producing the best protein-ligand affinity [17]. PrankWeb is a tool that helps in predicting the ligand binding sites. Two pockets were found in the protein FTO and selected the best site of them was by using the pocket score.

PyRx is a virtual tool for computer-aided drug creation that aids in the visualisation of interactions between several chemicals and potential therapeutic targets. A protein molecule was loaded and transformed into a macromolecule for autodock. Structured Data Format (SDF) anatomization is carried out by PyRx utilising OpenBabel, and options for ligand molecule energy minimization are also provided. OpenBabel is utilised to do energy minimization, and the GUI provided by it can be used to modify energy minimization parameters. The AutoDock Ligand format (PDBQT) conversion option is available in PyRx. Therefore, we immediately inserted ligand molecules, minimised them, and then changed them into autodock ligands [15].

Vina and autodock wizards are included with PyRx. Vina uses an innovative gradient optimisation technique for its local cumulation process. An optimisation technique from a single evaluation, the calculation of the gradient effectively provides a feeling of direction. We picked a vina wizard to dock the protein with ligands so we used a grid that was chosen for a particular pocket and docked the protein with the appropriate ligands. Binding affinities were noted and converted docked compound into pdb format [6].

The 2-D schematic illustrations of protein-ligand complexes are produced with the aid of the LIGPLOT software. We can decipher the atom accessibilities, hydrogen bonds, and hydrophobic interactions that occur between molecules. Some predictions for drug-likeness made by machine learning include Support vector machines (SVM), artificial neural networks (ANN), recursive partitioning (RP), and naive Bayesian (NB) [16].

Using the Lipinski rule of five, we compared protein-ligand interactions. Analysing the drug-likeness of the molecule is necessary to determine whether it is well absorbed when taken orally. Octanol/water partition coefficient (ALogP) 5, molecular weight (MW) 500, H-bond donors (HBDs) 5, and H-bond acceptors (HBAs) 10 are the parameters. This means that we should consider something to be inactive orally if two or more of the four rules are broken [4].

3. Results

In AutoDock Vina, molecular docking was done for five different compounds, and the top 10 poses were then found. The protein and chemical had a strong

binding relationship, which was validated by the binding affinity with the lowest score. Table 183.1 shows that the binding energies of the five compounds ranged from -8.8 to -9.1 kcal/mol. The energy range verified the chemicals' ideal binding. Chrysophanol displayed the lowest binding affinity i.e., -9.1 kcal/mol among

the five chemicals. When compared to other chemicals, it displayed the highest affinity.

Among all the substances in Table 183.1, Chrysophanol had the highest binding affinity (-9.0 kcal/mol). When compared to resveratrol, it is displaying the best affinity. Ligplus was used to create the intricate visualisation, which allowed us to see the interactions between the Chrysophanol and FTO proteins (Figure 183.1). Chrysophanol, an anthraquinone, functions as an inhibitor for FTO protein and treats obesity since the Lipinski rule (Table 183.2) determined that the compound's qualities were satisfied.

4. Discussion

The structural interactions between the protein that causes obesity and a few new lead chemicals produced the most effective combination in this investigation for blocking the protein [20]. Anthraquinones and non-flavonol polyphenol compounds demonstrated superior binding affinity to the former group. Utilizing Ligplus, the newly generated compounds were tested to examine how the compounds interacted [24]. The interactions of each ligand with the protein FTO via hydrogen bonds and hydrophobic interactions are shown in Table 183.1. More substances had binding interactions of at least 5. But in this case, the degree of interaction between the two compounds was used to choose the optimal compound [11]. Between 8.0 kcal/mol and 11.71 kcal/mol are the best binding energies for docked molecules. The interactions between the FTO protein and its associated ligands are depicted in two dimensions in Figure 183.2.

To find the most effective drug to treat the ailment, the binding affinity was acquired from the visualisation tool PyRx [13]. Resveratrol, a template ligand, has a binding affinity of -8.9 kcal/mol, although other non-flavonoids also displayed a lower affinity. In an unusual finding, all of the anthraquinones showed binding energies between 7.4 and 9.1 kcal/mol. Chrysophanol among them demonstrated the highest binding affinity (-9.1 kcal/mol). In addition, the best binding energies were demonstrated by Physcion, with -8.0 kcal/mol, and Aloe-emodin, with -8.6 kcal/mol.

The MOLINSPIRATION program [12], is used to estimate these properties. It is necessary to compute the molecular weight, and the octanol-water partition coefficient (Log P). Chrysophanol has a molecular weight of 254.24 g/mol, a log P of 3.54, two hydrogen bond donors, and four hydrogen bond acceptors. This compound is the best since it complied with the Lipinski rule of five [22] (p. 9). Table 183.2 offers an analysis of Lipinski's rule characteristics of various chemicals.

5. Conclusion

According to our research study, Chrysophanol will be the most effective human FTO protein inhibitor compared to other substances like Resveratrol. Throughout these molecular docking studies, the optimal interactions between the protein and the ligand have been observed. Finding the appropriate ligand was made easier with the use of binding energies and H-bond interactions. Chrysophanol is a natural anthraquinone that has been extensively studied for its wide range of therapeutic applications. We think that the information presented here can offer people who are obese a chance to regain their healthy lives and that it may also be used to develop the most effective anti-obesity medications.

Abstract: This research is intended to heighten the precision in forecasting Acral Lentiginous Melanoma (ALM) by utilizing a creative prediction approach. This approach deploys the Random Forest (RF) algorithm and involves a contrastive assessment with the Naive Bayes (NB) algorithm. Materials and Methods: Acquiring data using Kaggle database, the study employed a sample size of forty individuals, separated into two groups of twenty, to increase the precision of predicting Acral lentiginous melanoma disease. G-power was used for the analysis, with alpha, beta, and a 95% confidence interval of 0.05, 0.2. After implementing both RF and NB algorithms using an equal number of data samples, the findings indicated that RF had a greater accuracy rate when it came to predicting Acral Lentiginous Melanoma disease. Results: The research's introduced Random Forest (RF) algorithm demonstrated an impressive predictive performance, achieving a 93.78% accuracy in forecasting Acral Lentiginous Melanoma (ALM). This outperformed the Naive Bayes (NB) classifier, which achieved a lower accuracy rate with 82.60%. By means of the analysis, it came to light that the study's significance level stood at $p = 0.001$ ($p < 0.05$), highlighting a statistically substantial divergence between the two algorithms in their predictive accuracy for Acral Lentiginous Melanoma disease. Conclusion: The outcomes of this investigation have revealed the effectiveness of applying the Random Forest method in discerning Acral Lentiginous Melanoma (ALM). Furthermore, these results emphasize the significance of integrating advanced machine learning approaches to improve the early detection of this specific type of skin cancer.

Keywords: Acral lentiginous melanoma disease, random forest, Naive Bayes, innovative prediction technique, machine learning, accuracy, diseases

1. Introduction

In recent years, machine learning algorithms have been used to predict the development of ALM, with the aim of improving early diagnosis and treatment [3]. This study set out to intricately evaluate and draw a meticulous comparison between the operational effectiveness of two distinct machine learning models: random forest and naive Bayes. The training phase involved instructing both the random forest and naive Bayes algorithms using the training subset, and their performance was gauged against the test subset. The results of this study indicate that the random forest algorithm outperforms the naive Bayes algorithm in predicting ALM. This suggests that the random forest algorithm may be more effective in identifying patients at risk of developing ALM, which could improve the ability to diagnose and treat this aggressive type of skin diseases early [5]. Both Support Vector Machine and Random Forest algorithm were used to classify pigmented skin lesions as acral lentiginous melanoma or benign. Deep learning algorithms, specifically a random forest are

used to classify dermoscopic images of pigmented skin lesions as acral lentiginous melanoma or benign. In reality, many of the features used to predict ALM, such as demographics, clinical characteristics, and laboratory test results, are likely to be correlated. In this study, an Innovative Prediction Technique using Random Forest was proposed to improve the prediction of Acral Lentiginous Melanoma in comparison to the traditional Naive Bayes method. The performance of the proposed method was evaluated by comparing it to the Naive Bayes method in terms of training performance and classification accuracy.

2. Materials and Methods

The initial group employed a Naive Bayes algorithm, whereas the second group employed a state-of-the-art Random forest method which is an innovative prediction technique. The Python software was used to produce the findings and the sample size was based on earlier research with a confidence interval of 95%, with a threshold of 0. Naive bayes by utilizing Bayes' theorem, Naive Bayes can compute the likelihood of a class label by taking into account the evidence provided by input features and the prior probability of the class. Bayes' theorem can be used to calculate the probability that a given sample belongs to a particular class, given the feature values of the sample. The basic idea of the naive Bayes algorithm is to assume that all features are independent, which simplifies the calculation of the posterior probability Naive Bayes algorithm does not take into account the relationship between features, which often results in a high bias and lower accuracy in comparison to more sophisticated models such as Random Forest. One of the main disadvantages of naive Bayes is that it makes a strong assumption of independence between features. The basic idea behind a decision tree is to use a tree-like structure to represent a set of decisions and their possible outcomes. One of the key advantages of random forests is that they are less prone to overfitting than a single decision tree. This is because each individual decision tree in the forest is trained on a different subset of the data, and different subsets of features are used at each node of the tree, which reduces the chances of overfitting. Additionally, by averaging the predictions of many decision trees, random forests are able to reduce the variance and bias of the overall model.

2.1. Procedure

1. Acquire the necessary data on Acral Lentiginous Melanoma for training the Random Forest model.
2. Preprocess the acquired data to ensure it is clean, complete, and structured.
3. Split the preprocessed data into training and testing sets.
4. Train the Random Forest model using the training set and fine-tune its parameters to obtain the highest accuracy.
5. Validate the trained model using the testing set to check its performance and ensure it is not overfitting the training data.
6. Evaluate the model's accuracy and identify any areas for improvement.

2.2. Statistical analysis

The tests in this study, which compared the accuracy of two algorithms (RF and NB) for predicting acral lentiginous melanoma disease, were run using Python (Opasic et al. 2020) on a Windows 10 computer with specific hardware specifications. The examination of

Table 184.1. Calculation of evaluation metrics encompassing the RF and NB classifiers unveils a disparity: the RF classifier attains a remarkable accuracy rate of 93.78%, overshadowing the NB algorithm's 82.60%. This underscores the RF classifier's proficiency in identifying Acral Lentiginous melanoma, owing to its significantly higher accuracy rate

Sl. No.	Test samples	Accuracy Rate	
		RF	NB
1	Test 1	90.23	80.10
2	Test 2	90.54	80.23
3	Test 3	90.36	80.19
4	Test 4	91.34	80.92
5	Test 5	91.12	81.92
6	Test 6	92.56	81.01
7	Test 7	93.35	81.85
8	Test 8	93.36	82.28
9	Test 9	93.45	82.58
10	Test 10	93.54	82.34
11	Test 11	90.23	80.10
12	Test 12	90.54	80.23
13	Test 13	90.36	80.19
14	Test 14	91.34	80.92
15	Test 15	91.12	81.92
16	Test 16	92.56	81.01
17	Test 17	93.35	81.85
18	Test 18	93.36	82.28
19	Test 19	93.45	82.58

Average results		93.78	82.60

Source: Author.

Table 184.2. An analytical comparison has been undertaken between the RF and NB classifiers, displaying their mean, standard deviation, and mean standard error figures. Within the t-test framework, the accuracy metric takes center stage. The RF method proposed here exhibits a mean accuracy rate of 93.78%, in contrast to the mean accuracy of 82.60% for the NB algorithm. Notably, the standard deviation for the RF is calculated at 0.67893, whereas the NB algorithm demonstrates a standard deviation of 1.67839. Additionally, the mean standard error for the RF is determined to be 0.33248, while for the NB approach, it stands at 1.78293

Group		N	Mean	Standard Deviation	Standard Error Mean
Accuracy Rate	NB	20	82.60	1.67839	1.7893
	RF	20	93.78	0.67893	0.33248

Source: Author.

Table 184.3. By means of statistical scrutiny, the independent variables of the RF were contrasted with those of the NB classifier. Importantly, the accuracy rate emerged as significant at the 0.038 level. To compare the RF and NB algorithms, an independent samples T-test was employed, utilizing a 95% confidence interval and a notable threshold of 0.77838. This T-test was carried out with a significance level of 0.001 ($p < 0.05$), while also addressing differences in means, standard errors, and the upper and lower intervals between the two algorithms

Group		Leven's Test for Equality of Variances		T-test for Equality of Means					95% Confidence Interval	
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	(Lower	(Upper)
Accuracy Rate	Equal Variances Assumed	119.87	0.0387	6.772	18	.001	112.87837	0.77838	111.87362	13.67292
	Equal Variances not Assumed			8.019	12.923	.001	111.5893	0.5469	110.37485	12.34582

test results involved the utilization of SPSS software for conducting a comprehensive statistical analysis… The means, standard deviations, and standard errors of the two sample groups were subjected to scrutiny through an independent sample t-test. This evaluation centered around the accuracy, treated as the dependent variable, while the independent variables encompassed the sample images.

3. Results

The performance metrics of the RF and NB classifiers for detecting skin diseases particularly Acral
Figure 184.2. A visual representation through a bar graph underscores the comparison between the accuracy rates of the Random Forest and NB models. The RF model prominently attains an accuracy rate of 93.78%, outperforming the NB model's 82.60% accuracy. A p-value of <0.05 clearly establishes a significant differentiation between the RF classifier and the NB classifier. Within the graph, the X-axis indicates the precision rates of the two classifiers, while the Y-axis presents the mean accuracy accompanied by a standard deviation (±1 SD) and a 95% confidence interval.

Source: Author.

Lentiginous melanoma are presented in Table 184.1. According to the table, the RF classifier has an accuracy rate of 93.78%, which is higher than the NB algorithm's accuracy rate of 82.60%. These findings suggest that the RF classifier surpasses the NB classifier in its ability to detect Acral Lentiginous melanoma, demonstrated by a notably elevated accuracy improvement.

In Table 184.2, a statistical juxtaposition between the RF and NB classifiers is presented, outlining their respective mean, standard deviation, and mean standard error values. Through the accuracy metric, the t-test facilitates a comparative assessment of these classifiers. The proposed RF technique showcases a mean accuracy of 93.78%, whereas the NB algorithm achieves a mean accuracy of 82.60%. With the RF, the standard deviation is reported at 0.67893, while the NB algorithm reflects a standard deviation of 1.67839. Furthermore, the mean standard error for the RF approach is 0.33248, whereas the NB algorithm yields a mean standard error of 1.78293.

Table 184.3 showcases the statistical assessment conducted on the independent variables of both the RF and NB classifiers. The accuracy rate was deemed significant at the 0.038 level, and the RF and NB algorithms were compared using a T-test for independent samples, with a 95% confidence interval and a significant threshold of 0.77838. The two-tailed, independent sample t-test considers the significance level of 0.001 and takes into account the differences in means, standard errors, and lower and upper intervals between the two algorithms.

In Figures 184.1a–184.1b the images which were given as one of the samples is depicted and its corresponding binary segmented outputs were given. Figure 184.2 depicts a comparison of the accuracy of the RF and NB classifiers. The RF model shows a higher accuracy rate of 93.78%, whereas the NB model has an accuracy rate of 82.60%. A p-value lower than 0.05 ($p < 0.05$) indicates a noteworthy distinction between the RF and NB classifiers. The X-axis of the graph portrays the precision rates of the RF and NB classifiers, while the Y-axis visually represents accuracy, complete with a standard deviation (±1 SD) and a 95% confidence interval.

4. Discussion

This study aimed to evaluate the performance of Random Forest (RF) algorithm which ia s innovative prediction technique for detecting Acral Lentiginous Melanoma diseases (ALM), and compare it to an existing Naive Bayes algorithm. To do this, classification techniques were applied to a dataset obtained from Kaggle, using Python for implementation. The models were trained on 80% of the data and tested on 20% of the data. The results showed that the RF approach achieved a higher accuracy rate of 93.78%, compared to the Naive Bayes method which had an accuracy of 82.6%. This suggests that the RF approach is more effective in accurately diagnosing ALM and also in making more efficient diagnoses.

Comparable investigations utilized a range of machine learning algorithms including decision trees, random forests, and support vector machines, to analyze dermoscopic images of acral melanomas. The outcome was a 91.7% accuracy rate, as indicated by the application of a random forest classifier. Computer-aided diagnosis (CAD) system was developed for acral melanoma using several machine learning algorithms, including K-nearest neighbors, random forests, and support vector machines. It achieved an accuracy of 93.4% using a random forest classifier. Several machine learning algorithms, including K-nearest neighbors, random forests, and support vector machines, on dermoscopic images of acral melanomas and benign acral nevi were analyzed with a accuracy of 94.4% using a support vector machine. However, the study has limitations with the sample size that was used and the results should be validated on a larger patient population. Further research should also be conducted to examine the factors that contribute to the development of ALM and to identify potential targets for early intervention.

5. Conclusion

This study set out to evaluate and draw a comparison between the performance of a random forest (RF) model and a Naive Bayes (NB) model in the context of detecting Acral Lentiginous Melanoma (ALM). The results revealed that the RF model had a superior accuracy rate, specifically it had a 95.60% increase in accuracy as compared to the NB model which had an accuracy of 88.75%.

185 Analyzing security vulnerabilities in consumer IOT applications using Twofish encryption algorithms comparing with DES algorithm

Sathish B.[1,a] and Anithaashri T. P.[2]

[1]Research Scholar, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Project Guide, Department of Computer Science and Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The aim of this study is to analyze security vulnerabilities in consumer Internet of Things (IOT) applications using the TwoFish encryption algorithm in comparison with the Data Encryption Standard (DES). Materials and Methods: For this study, a sample of consumer IOT applications will be selected and examined for their susceptibility to common security vulnerabilities. The TwoFish encryption algorithm will be implemented and analyzed against the DES algorithm to determine which provides the strongest level of encryption and protection. Security vulnerabilities that are commonly found in consumer IOT applications will be identified and analyzed using a combination of manual and automated testing techniques, such as fuzz and penetration testing. Results: The results of this study will provide an understanding of the security vulnerabilities and the effectiveness of the TwoFish encryption algorithm compared to the DES algorithm. The sample size is N=10 for each group and the jupyter notebook is used. Two sample groups were tested with 20 samples, with G-power as 80% with total sample size 450, 80% for training 360 and 20% for testing 90 and test results shows that the Twofish algorithm has an average accuracy of 82.46% for improvising the energy efficiency, which is significantly better than the DES algorithm accuracy of 76.73%. Avoid insights into the security vulnerabilities as well as the strength of the encryption algorithms for consumer IOT applications. At $p < 0.05$, the significance level was 0.021. Anticipated outcomes indicate that the two-tailed tests will demonstrate a statistically significant distinction between the two methods. In conclusion, it is found that the accuracy of the Twofish Encryption algorithm is significantly higher than that of the DES method.

Keywords: IOT, twofish encryption algorithm, DES algorithm, security threats, encryption, decryption

1. Introduction

The Internet of Things (IOT) has become increasingly popular in recent years, with consumer applications being developed for a variety of uses. However, the security of these applications is a major concern, as they are susceptible to various security vulnerabilities [5]. This study seeks to analyze the security vulnerabilities of consumer IOT applications using the TwoFish encryption algorithm in comparison to the Data Encryption Standard (DES) [14, 15]. The security vulnerabilities will be identified and analyzed using a combination of manual and automated testing techniques [14], such as fuzz and penetration testing. The results of this study will provide insights into the security vulnerabilities as well as the strength of the encryption algorithms for consumer IOT applications [5].

The efficiency of the DES and TwoFish encryption algorithms will be contrasted in order to determine which offers the highest level of security [16] and encryption [5, 15]. It is anticipated that the study's findings would help researchers better understand the

security flaws in consumer IOT applications and how TwoFish stacks up against DES [14]. Additionally [4, 6], the study may offer advice on how to protect consumer IOT applications from common security risks [3, 13].

Research gap in the existing system is on-demand self-service the services through several IOT devices which allows users to scale up or down their computing needs as needed, without (Inc., Wolfram Research, and Inc., n.d.) having to invest in expensive hardware and infrastructure. Research gap in the existing system is the lack of security in accessing the information of consumer utilizing IOT is addressed here. The suggested system's primary goal is to use the Twofish algorithm to secure IOT-enabled services. By combining Twofish security and evaluating its performance against the DES method, this work aims to increase classification accuracy. The suggested model enhances predictive analysis for Internet of Things applications.

2. Material and Method

2.1. Twofish encryption algorithms

With a block size of 128 bits and key sizes of 128, 192, and 256 bits, Twofish is a symmetric-key block cipher. It was one of the five finalists in the National Security Agency's (NSA) selection process for the Advanced Encryption Standard (AES) algorithm and is an enhancement over the AES algorithm. To encrypt data, Twofish combines substitution, permutation, and key-dependent operations [10]. It is impervious to known-plaintext assaults as well as differential and linear cryptanalysis. Twofish is a safe method that works well in many different contexts, particularly in consumer IOT applications.

Step 1: Select the encryption algorithm (Twofish) and the key size (128, 192, or 256 bits).

Step 2: Generate a random key from the selected key size.

Step 3: Set up the encryption algorithm with the key.

Step 4: Prepare the plaintext for encryption.

Step 5: Encrypt the plaintext using the Twofish algorithm.

Step 6: Output the ciphertext.

Step 7: To decrypt the ciphertext, the same key and algorithm must be used.

2.2. DES (Data Encryption Standard) algorithm

It is based on the Feistel network and has a key size of 56 bits and a block size of 64 bits. Data is encrypted using DES by first dividing it into 64-bit blocks, after which the data is subjected to a number of permutations and substitutions. Although it can withstand brute-force attacks, it is sensitive to linear and differential cryptanalysis. The Advanced Encryption Standard has largely supplanted DES, which is no longer regarded as secure (AES).

Step 1: Select the encryption algorithm (DES) and the key size (56 bits).

Step 2: Generate a random key from the selected key size.

Step 3: Set up the encryption algorithm with the key.

Step 4: Prepare the plaintext for encryption.

Step 5: Break the plaintext into 64-bit blocks.

Step 6: Encrypt each 64-bit block using the DES algorithm.

Step 7: Output the ciphertext.

2.3. Statistical analysis

Statistical analysis can also be used to monitor the effectiveness of new treatments or interventions, as well as to analyze the cost-effectiveness of different approaches to care. Using the SPSS statistical package,

Table 185.1. Accuracy and loss analysis of twofish security algorithm

Iterations	Accuracy (%)	Loss (%)
1	80.1	10.9

the analysis of mean accuracy for consumer security using novel Twofish algorithm and DES algorithm for consumer security with the total sample size N=450 calculated through Clin.Clac.com was carried out by applying an independent sample t-test with a significance level of p<0.05 to achieve 82.56% accuracy Images are the dependent variables, and the independent variables are frequency, modulation, and amplitude size.

3. Results

Twofish is a more secure algorithm than DES. However, twofish is slower than DES and may not be suitable for applications that require a high-speed encryption. With a sample size of ten, the suggested twofish and DES were run in Anaconda Navigator at various times. The expected accuracy and loss of twofish are shown in Table 185.1. The expected accuracy and loss of DES are shown in Table 185.2. For each algorithm, these ten data samples are used, together with their corresponding loss values, to compute statistical values that can be compared. It is evident from the data that the twofish mean accuracy. The mean accuracy values for DES and twofish are shown in Table 185.3. The twofish algorithm has a higher mean value than the DES algorithm, which is an older algorithm. However, because of its simpler structure and lower key length, the twofish algorithm is not as safe.

The independent sample T test results for twofish and DES with (p<0.05) are displayed in Table 185.4.

Figure 185.1. Comparison of mean accuracy of Twofish Security algorithm and DES algorithm. Twofish Algorithm (82.46%) gives significantly better accuracy than DES (76.73%) where X-axis gives the algorithms and Y-axis gives the mean accuracy of prediction.

Source: Author.

When analyzing the security of these algorithms, it is important to consider the cost of implementation and the time required for encryption in addition to the security. The twofish algorithm should be chosen if the security and complexity of the encryption is important, and the cost and time taken to implement the algorithm.

4. Discussion

Users have serious concerns about the security of consumer IOT apps since the devices are frequently linked to the internet and can be accessed by bad actors [9]. It

is crucial to use encryption methods like the TwoFish and DES algorithms to secure the security of these applications [8]. Using the TwoFish and DES algorithms [17], we will examine and contrast the security flaws in consumer IOT applications in this presentation in Figure 185.1.

One of the most secure encryption techniques now in use is the TwoFish algorithm, a symmetric block cipher that employs 256-bit keys [12]. It has a small memory footprint and resists brute-force attacks. The DES algorithm, on the other hand, is an older encryption method that uses 56-bit keys and is less safe than TwoFish [2]. It has a larger memory footprint and is more prone to brute-force attacks.

When comparing the TwoFish and DES algorithms [1] to examine consumer IOT application security flaws, the TwoFish approach is the more secure option. It has a bigger key size, is less susceptible to brute-force assaults, and uses less memory [1, 11]. In contrast, the DES algorithm is not as secure and is subject to brute-force attacks. It also has a bigger memory footprint.

5. Conclusion

When examining the security flaws in consumer IOT applications, the TwoFish method is the better secure option. Compared to the DES algorithm, it has a bigger key size, is more resistant to brute-force attacks, and uses less memory. Users can be confident that their data is safer and more secure when using the TwoFish algorithm. This research study compared the accuracy of the Twofish algorithm (82.46%) and DES algorithm (76.73%) which shows that the Twofish algorithm is significantly better than the DES algorithm.

186 Bacterial lipase enzyme production by *Bacillus licheniformis* MTCC8725 in solid-state fermentation by comparison of coconut oil and olive oil as substrates

Dharmalingam Karunya[1,a] and Ramaswamy Arulvel[2]

[1]Research Scholar, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Research Guide, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The aim of this study was to produce lipase using *Bacillus licheniformis* MTCC8725 from olive oil and coconut oil and to compare the performance using both novel substrates. Materials and Methods: The use of bacterial strains in this investigation was an effective component of the methodology. The steps of solid-state fermentation were followed by enzyme extraction in the determine technique to culture the *Bacillus licheniformis* (MTCC8725) strain Gibson 46. A titrimetric method was used to the lipase activity. Coconut oil and conventional olive oil are the major novel substrates. The experiment was carried out in the bioengineering lab at Saveetha School of Engineering. Results: Four samples were taken from each group, with 80% G power and statistical significance (p=0.02). Independent sample T-test was performed and the sample size was calculated to 8. Coconut oil produced more lipase than olive oil when cultured under the optimal conditions of 50°C, pH 7.0, and 70% (v/w) moisture content. Lipase activity in coconut oil was 14.29 U/mL and 13.72 U/mL in olive oil. Discussion and conclusion: The results were discussed with the other research articles and justified. Limitations and future scope of the study were discussed. The synthesis of *Bacillus licheniformis* (MTCC8725) lipase using coconut oil and olive oil is the subject of this study, which is the first of its kind. Coconut oil produced more enzymes compared to the byproducts from olive oil in the study. According to the study, coconut oil produced a higher yield than olive oil. The lipase activity for every single parameter under specific conditions was discovered.

Keywords: Enzyme production, coconut oil, novel substrates, olive oil, productivity, incubation period

1. Introduction

Lipases are a type of enzyme that catalyze the hydrolysis of fats and oils, breaking down triglycerides into their component fatty acids and glycerol molecules. They are primarily produced in the pancreas, but can also be found in other parts of the body such as the stomach, liver, and adipose tissue [10]. Lipases are critical for the digestion and absorption of fats in the body, and play an important role in maintaining lipid homeostasis. They are also widely used in industry for a variety of applications such as food processing, biodiesel production, and laundry detergents. There are many different types of lipases, each with its own specific characteristics and functions. Some lipases are activated by specific cofactors or ions, while others require a particular pH or temperature range to function optimally. Lipases can also differ in their substrate specificity, with some enzymes being able to hydrolyze a wide range of fats and oils, while others are more specific in their action. Overall, lipases are important enzymes with a wide range of biological and industrial applications, and their study continues to be an active area of research. The lipase in food industries are used in the production of cheese, yogurt, butter, and other dairy products, where it is used to modify the flavor and texture of the final product. It is also used in the baking industry to improve the texture and shelf life of

baked goods, such as bread and pastries. Lipase is used in the production of drugs and other pharmaceutical products, such as liposomal formulations, where it is used to break down lipids and improve drug delivery [6]. Lipase also has promising applications in detergent industries, cosmetics as well as biofuel industries. Overall, lipase is a versatile enzyme with a wide range of applications in various industries, and its importance is increasing as more and more industries seek to develop sustainable and environmentally friendly processes. The total number of research publications from Science Direct and Google Scholar combined was 2082. *Bacillus licheniformis* is a rod-shaped, spore-forming bacterium that belongs to the genus Bacillus. It is a common soil bacterium and can also be found in various other environments, including water, dust, and animal feed. *B. licheniformis* is known for its ability to produce a variety of enzymes, such as proteases, amylases, and lipases, which have important industrial applications (Yang, Lio, and Wang 2012). It is also used as a probiotic in animal feed to promote animal health and growth. While *B. licheniformis* is generally considered to be non-pathogenic, it can occasionally cause infections in humans, particularly in immuno-compromised individuals. It has been implicated in a variety of infections, including sepsis, pneumonia, and wound infections. Overall, *B. licheniformis* is a versatile and important bacterium that has numerous industrial and scientific applications, but it should be handled with care to prevent any potential health risks. The production of lipases can be optimized using various techniques such as response surface methodology, artificial neural networks, and genetic algorithms. These optimization techniques can help to improve the yield of lipases and reduce the cost of production [2]. Immobilization of lipases can improve their stability and reusability, and it can also reduce the cost of production. Various immobilization techniques such as adsorption, entrapment, and covalent binding have been used for the immobilization of lipases. Genetic engineering can be used to modify the properties of lipases, such as their substrate specificity, thermal stability, and pH stability [16].

Solid state fermentation (SSF) is a bioprocess in which microorganisms grow on solid substrates with low moisture content. In SSF, microorganisms obtain nutrients from the solid substrate and produce various metabolites, such as enzymes, organic acids, and secondary metabolites. SSF has several advantages over liquid fermentation, including low capital investment, reduced energy consumption, and high product yield [1]. It is also less susceptible to contamination and can be used to produce a wide range of products, including enzymes, organic acids, and antibiotics. Some of the applications of SSF include the production of enzymes, organic acids, antibiotics, and bioactive compounds.

SSF can be carried out using both aerobic and anaerobic microorganisms, depending on the product being produced and the desired process conditions. Aerobic SSF allows for the production of products that require oxygen, while anaerobic SSF is suitable for products that can be produced under anaerobic conditions, such as certain organic acids and biofuels. The use of SSF has several advantages over liquid fermentation, including higher product yield, lower energy consumption, and reduced capital investment. The aim of the study was to demonstrate that the production of enzyme by *Bacillus licheniformis* was more effective when specific raw materials were employed, such as olive oil, melon waste, sunflower oil and coconut oil, and butter oil [4]. The effects of various substrates and influencing factors, such as pH, incubation period, temperature, the sources of carbon, and the availability of minerals, were all carefully examined.

2. Materials and Methods

The experiments were performed in the bio-engineering laboratory of the Saveetha School of Engineering. A total number of 2 groups were taken. Each group consisted of 4 samples. The total sample size was calculated as 8 according to (Kane, Phar, and BCPS n.d.) with 80% G power.

2.1. Substrates preference

Olive oil and coconut oil were used for the current study. These substrates were purchased from nearby markets.

2.2. Bacterial strain

Bacillus licheniformis (MTCC8725) was provided to us by the Microbial Type Culture Collection Center and Gene Bank in Chandigarh, India. We employed nutritional agar (NA), which has a final pH of 7.1, agar, peptone, yeast extract, beef extract, and sodium chloride (NaCl), to revive the culture and subculture it at 30°C. The stock culture was preserved at a freezing temperature of -20°C.

2.3. Preparation of inoculum of Bacillus licheniformis *MTCC8725*

The pre-culture medium of *Bacillus licheniformis* MTCC8725 was nutrient broth media. It included Peptone 5 g/L, NaCl 5 g/L, Beef Extract 1 g/L, and Yeast Extract 2 g/L. The pre-culture was incubated at 37°C with 180 rpm shaking for 16 hours. The primary components of the basic culture medium for lipase productivity were glucose (10 g/L), peptone (10 g/L), yeast extract (5 g/L), sodium chloride (5 g/L), K_2HPO_4 (3 g/L), K_2HPO_4 (1 g/L), calcium chloride (2 g/L),

magnesium sulphate in water (2 g/L), (NH4)2SO4 (2 g/L), and olive oil (2% (v/v).

2.4. Solid-state fermentation

Many mixtures of olive oil and coconut oil were examined by setting the total weight to 5 g to produce lipase. The pH and moisture content of the substrate combination was kept constant by adding 0.05M potassium phosphate buffer (K_2HPO_4 and K_2HPO_4) to a 250 mL Erlenmeyer flask along with 5 g of the substrate mixture. By autoclaving them for 15 minutes at 121°C and 15 pressure, the flasks were sterilized. *Bacillus licheniformis* (MTCC8725) was applied to the solid substrate as an inoculant at a rate of 4% (v/w) after chilling. A 72-hour incubation period took place in the flask at 30°C. The solid substrate that contained the bacterial biomass was periodically taken out in a sterile environment. The fermented mixture was filtered and properly blended to obtain a completely normal sample. A solution containing 1% (w/v) Triton X-100 and 1% (w/v) NaCl was diluted in 10 mL with 0.5 g of substrate. A mortar and pestle were used to crush this mixture. Whatman No. 1 filter paper was used to filter the end product. The residue that was still on the filter paper was dried at 70°C for 24 hours to determine the dry solid weight. After that, the filtrate underwent a 10-minute centrifugation at 10,000 rpm. The lipase test's final supernatant served as a source of enzymes [8].

2.5. Enzyme extraction

The solids that had undergone fermentation were taken out of the reactor and put in a glass flask thereafter. Sodium phosphate buffer was added to the flask, which was then placed on a rotary shaker (200 rpm) at 35°C for 20 minutes (135 mL, 100 mM, pH 7.0). The material was physically crushed to get the extract, and the extract was centrifuged after that (3000 rpm,2 minutes).

2.6. Lipase assay

The modified titrimetric approach was used to measure lipase activity. The reaction mixture was then combined with and shaken for 30 minutes at 30°C and 130 rpm. 1 mL of the enzyme extract, 20 mL of 0.1 M potassium phosphate buffer, and 5 mL of olive oil emulsion substrate were added to the reaction mixture. After that, this reaction combination was stopped by adding 15 mL of an acetone-ethanol (1,1) mixture. Fatty acids were released in amounts that were titrated against 0.05 N NaOH up until the point when the solution became pink. The enzyme was introduced into blank tests just before titration. The amount of enzyme required to release 1 mol equivalent of fatty acid (measured in mL per minute) under typical test

circumstances is referred to as one unit of enzyme activity. In general, units per mL or units per g of the dry substrate can be used to represent enzyme activity. To calculate the lipase activity, the following formula as shown in (1) was utilized in the test technique.

$$Lipase\ activity\ (U/L) = (A * C/V) * 10^6 \qquad (1)$$

A= mL of NaOH consumed per minute
U= μ moles of fatty acids released per minute
C= Concentration of NaOH in m moles/L
V= enzyme sample volume in μL. 10^6 converts sample volume to litres.
U/mL = μ moles of fatty acids released per minute per mL of crude enzyme.

2.7. Optimization of parameters for lipase production

Various productivity-related factors were adjusted, including pH, temperature, inoculum size, incubation period, agitation rate, and carbon sources to observe the different lipase activities in both olive oil and coconut oil under solid-state conditions.

2.8. Optimization of inoculum size

The inoculum was made up of olive oil and coconut oil which were collected in quantities of 5g/5 mL each and put in 250 mL culture flasks with pH 5.5. The growth of the bacteria and the synthesis of lipase may be influenced by the inoculum size. The enzyme was then extracted and measured from each batch following a 36-hour incubation at 50°C with 150 rpm shaking.

2.9. Effect of incubation temperature and pH

The pH level was altered so that it may be possible to investigate how pH and temperature affect the process via which lipase is made. As it was found that the lipase enzyme has an acidic nature, the pH levels were kept at a constant level of 7, seed cultures were added, and the mixture was then shaken in an incubator at 150 revolutions per minute.

A titrimetric method was used to evaluate the lipase activity after a 72-hour incubation period. By analyzing the effects of temperatures at a constant level of 50°C after 72 hours, improved lipase activity was recorded in a cell-free broth at a temperature that was deemed to be acceptable [9].

2.10. Effect of agitation rate

The broth in a 250 mL Erlenmeyer flask was stirred more quickly by adding 10% (v/v) of the bacteria that produce enzymes. Following that, doses of the

inoculum were administered at 60, 90, 120, 150, and 180 rpm. After 72 hours, the broth was taken out and put through a colourimetric assay to find out if lipase was present. The production broth was incubated at several volumes to find the most beneficial production volume. The broth was collected after 72 hours and put through a colourimetric test to check for lipase activity [7].

2.11. *Effect of carbon sources*

The synthesis of lipase was influenced by a range of carbon sources, such as lactose, glucose, fructose, ribose, and sucrose. Each was put to the test by incorporating the 15 g/l starch concentration into the manufacturing medium that was initially intended for it. The lipase activity was evaluated following a 72-hour incubation period [13].

2.12. *Statistical analysis*

The results, which comprise mean, standard deviation, and standard deviation error, were calculated using IBM SPSS Software Version 26. The inoculum size and agitation rate were the dependent factors, whereas lipase activity (U/mL) was the independent variable. To evaluate the statistical significance of inoculum size and agitation rate, a t-test for independent samples was conducted.

3. Results

3.1. *Cultivation of microbial culture*

A rod-shaped, aerobic, thermophilic bacteria *Bacillus licheniformis* (MTCC8725) was employed in the

current studies to create an extracellular lipase. On an MB medium with 1% (v/v) fructose, the strain was regularly subcultured to sustain it. They were preserved for later use. The culture stocks of *Bacillus licheniformis* (MTCC8725) were created in glycerol (25% v/v; culture) and kept at -20°C.

3.2. Optimization of inoculum size on lipase production

A 36-hour seed culture inoculum at 5% (v/v) was added to the production broth, and at 50°C, an enzyme concentration of 0.481U/mL was produced. There is a little rise in lipase activity after 5% inoculum concentrations as shown in Table 186.1. The inoculum is composed of carbon sources in Table 186.1.

3.3. Effect of temperature on lipase production

A constant temperature of 50°C was kept so that the enzyme activity for coconut oil was found to be 13.84 U/mL and for olive oil it was 12.56 U/mL, showing that coconut oil generated a greater output as shown in Figure 186.1. Lower temperatures of around 30°C resulted in a slower rate of enzyme production; high temperatures were found to cause *Bacillus licheniformis* (MTCC8725) to grow more slowly.

3.4. Effect of pH on lipase production

The pH level of 7 resulted in olive oil showing a lipase activity of 11.29 U/mL whereas coconut oil had 11.98 U/mL as shown in Figure 186.2. *Bacillus licheniformis* (MTCC8725) survival was diminished when the pH is elevated beyond the optimal point and the enzyme activity is decreased when the pH falls below the perfect point in Table 186.2.

3.5. Effect of agitation rate on lipase production

The rpm was adjusted, and the agitation rate was determined (60–180). At rpm 150, 0.438 U/mL of maximum lipase activity was noted. To reduce lipase activity on either side, the rpm was adjusted as shown in Table 186.2.

3.6. Effect of incubation period on lipase production

The incubation period was maximized and the best time to gather the material for lipase production was identified. The enzyme activity was assessed for 72 hours. During each incubation period, the enzyme activity on each of the novel substrates varied. The lipase activity was analyzed during the incubation period.

3.7. Effect of carbon sources on lipase production

Each type of carbon source was tested at a concentration of 1.0% to see how it would affect how much lipase the broth could produce and maximize. Every carbohydrate utilized in the experiment had a direct impact on the lipase activity. The control includes all of the components that have been optimized up to this point, as well as 1.0% (v/v) emulsified fructose as shown in Table 186.3.

3.8. Growth of Bacillus licheniformis MTCC8725

Inoculating after 72 hours, 10% (v/v) of the 36-hour-old seed culture was added to the production broth, and this resulted in the development of the lipase activity for coconut oil 14.29 U/mL and olive oil 13.72 U/mL. To obtain the cell-free broth, the culture broth is centrifuged at 10,000 x g for 10 minutes at 4°C. The presence of lipase is next determined with p-NPP after this cell-free

broth has been filtered using Whatman filter paper no. 1. To account for the increased *Bacillus licheniformis* (MTCC8725) production, the inoculum size was modified. In the cultivation conditions, the microbial strain was very effectively shielded from contamination.

4. Discussion

4.1. Production of lipase from solid-state fermentation

A process known as "solid-state fermentation" (SSF) takes place in a solid matrix, also known as a "inert support" or "support/substrate," with either very little or no free water. This is because the substrate needs moisture in order to promote microbial growth and metabolic activity. The ability of microorganisms, like bacterial and fungal cells, to withstand catabolic repression (inhibition of enzyme production), even in the presence of plentiful novel substrates like glycerol, glucose, or other carbon sources, is one of the most important phenomena linked to SSF [15]. Solid-state fermentation is the term used to describe the growth and metabolism of bacteria on a solid, moist substrate in the absence of free-flowing water. The investigation of the lipase activity used several cutting-edge substrates, such as coconut and olive oils.

4.2. Optimization of inoculum size

The method by which the inoculum size was maintained constant should lead to increased lipase activity. Lower inoculum size with increased enzyme production. Additional carbon sources including sugars, alcohols, polysaccharides, whey, amino acids, and other complex sources have a big impact on production. To keep track of pH levels, use a pH meter, a device that measures pH fast. It represents lipase, an enzyme with very high acidity. The pH was maintained at roughly 5, keeping the lipase enzyme from becoming unstable at levels above 10. Across a wide pH range, *Bacillus licheniformis* (MTCC8725) SB-3 lipase is active (pH 3–12) [3].

4.3. Enzyme extraction

Certain enzymes are utilized in the enzyme-assisted extraction process to break down the source material's cell walls and boost extraction yield. Enhancing the quantity of bioactive that is fully recovered from the source materials can be achieved by combining this procedure with numerous different techniques. The enzyme lipase was used to break down the cell walls of oilseeds. Oilseeds become softer and more porous when oil sacs that are enclosed in the cell walls of the seeds are released with the help of enzymes. The oil, protein, and polysaccharides in oil seeds can all be easily separated for further processing by using enzymes.

When the enzyme has been extracted, the lipase test is utilized to gauge lipase activity in the article [11].

4.4. Effect of pH and temperature

Temperatures between 30 and 60°C were normally ideal for enzyme production. A constant to track the lipase activity on coconut and olive oils, temperature and pH were established and one of these novel substrates offered the highest output. Sunflower oil generated more lipase than olive oil, according to laboratory testing and statistical analyses. In the article [18], the lipase activity at 50°C was observed as 11.43 U/mL and at pH of 7 the lipase activity was found to be 10.57 U/mL which shows that the current study gave a better yield.

4.5. Lipase activity on titrimetric method

Under test circumstances, 1 mol of fatty acids may be produced per minute with the enzyme lipase at a rate of one unit (U) of lipase activity. Units of a dry substrate expressed as a mL or g.

Are two common ways to express enzyme activity. By using a formula that was provided in the lipase assay, the lipase activity was obtained for both olive oil and coconut oil. The findings demonstrated that olive oil made under circumstances that were optimal for the long-term synthesis of lipase had a greater yield in the article [14].

4.6. Limitations of the study

The expensive microbial fermentation technique necessitates specialized machinery and infrastructure, which were the bottlenecks in lipase manufacturing. The complexity of the fermentation process may make it difficult to scale up lipase productivity from a lab to an industrial scale. A superior fermentation process might justify the greatest yield because solid-state fermentation produced a smaller amount of output. Certain molecular approaches that manufacture lipase at maximal levels in a pure form can overcome limitations in the usage of lipase caused by their high cost of productivity [12].

4.7. Future scope of the study

Future lipase production will be used in a variety of research and development domains, where it has interesting applications. When microbes are genetically modified, lipases can be produced in greater quantities and have better physical characteristics. Industry verticals such as food, pharmaceutical, leather, cosmetic, and detergent verticals are potential applications. The uses of lipase described above have bright futures.

5. Conclusion

The good activity of *Bacillus licheniformis* (MTCC8725) lipase was achieved by modifying a

variety of variables, such as carbon sources, temperature, pH, and inoculum size. The process of producing lipase via solid-state fermentation had positive outcomes. The coconut oil had a lipase activity of 14.29 U/mL, while the olive oil had a lipase activity of 13.72 U/mL after a 72-hour fermentation. The best immobilization strategy has to be selected to maximize the sustained productivity and activity of lipase. The findings were shown when temperature and pH factors were changed. Coconut oil had a lipase activity of 13.54 U/mL at 50°C, whereas olive oil had a lipase activity of 12.86 U/mL. Coconut oil had a lipase activity of 11.98 U/mL and olive oil had a lipase activity of 11.29 U/mL at a constant pH of 7. The results were obtained after a 72-hour incubation period. Under ideal growth conditions, the *Bacillus licheniformis* (MTCC8725) considerably had the highest lipase activity. $p = 0.02$ ($p < 0.05$) is a statistically significant value obtained from a T-test between groups using independent samples.

Abstract: This study's main goal is to quantify the amount of biogas produced in a biodigester during the anaerobic breakdown of cow manure and cauliflower stems. Materials and procedures: On day 14, the waste samples (cow dung and cauliflower stem) were gathered and subjected to anaerobic treatment in order to produce the most biogas possible. A smart biogas meter was used to calculate the volume of biogas generated by each group. The sample size was determined to be 28 (α=0.05, 95% confidence interval, and 80% G power) with two groups, each having a sample size of 14. Findings: For fourteen days, the biodigester was fed waste samples, including cow dung and cauliflower stem. The biodigester yielded approximately 12.45 m³ of biogas from the operation of cauliflower stems, and 20.98 m³ of biogas from cow manure. The findings of an independent sample T-test showed that cow dung created more biogas than the cauliflower stem. A substantial difference ($p<0.05$) is observed between the two groups. The p value is 0.024. Conclusion: According to this study, cow manure treated anaerobically produces more biogas than cauliflower stem. The significance threshold for the investigation was set at p=0.024 ($p<0.05$). This demonstrates that there is a statistically significant difference between the test groups.

Keywords: Fossil fuels, environment, food waste, anaerobic treatment, cow dung, energy

1. Introduction

Recently, in modern society, the need to use energy has increased due to an increase in world population growth because of which the current supply of energy is more likely dependent on fossil fuels for supporting their needs 61 [10]. Animals and plants that have decomposed into fossil fuels. These fuels, which include carbon and hydrogen and may be burned to produce energy, are found inside the crust of the Earth. Because using fossil fuels releases greenhouse gases, which are the primary cause of global warming, and because there aren't enough resources,, there is a need to implement an alternative energy resource to these fossil fuels 2 [9]. Biogas is one such alternative, renewable resource, obtained when biowastes are digested by certain microorganisms under anaerobic conditions. Energy is produced from those wastes after they have been broken down [14]. Biogas production is an efficient way to turn trash into a useful resource by using it as an anaerobic digestion substrate. A popular method for creating biogas from organic waste streams that come from various sources is anaerobic digestion, such as industrial, agricultural, and municipal solid waste. In terms of total solid content, this procedure can be run in both liquid and solid forms 273 [3, 8].

In recent years, a great deal of research on the creation of biogas from cauliflower waste has been published. The overall quantity of published papers by Google scholar is 15 research articles and Science Direct published 2 articles. In [11] research work, Anaerobic digestion was carried out on an equal amount of slurry in the biodigester for a four-week retention period, with weekly measurements of gas outputs (Alvares and Liden) demonstrated that 0.3 m³/kg of biogas was created by the semi-continuous co-digestion of cow manure with fruit and vegetable wastes [6] presented a thorough analysis of the anaerobic digestion procedure, which

was regarded as one of the most practical methods for recycling the organic portion of solid wastes. Subsequent investigation revealed that 88% of the biogas generated by anaerobic digestion of fruit and vegetable waste was generated in a batch reactor. Another study by [5] worked on the generation of biogas from four commonly produced vegetable wastes (corn cobs, cauliflower, cabbage, and bananas). Additionally, two particle size fractions (less than 75 m, 75–125 m) and several pyrolysis temperatures between 300°C and 600°C were taken into consideration.

The research gap identified that the currently used organic waste for energy production produces low yield of biogas. The need for an efficient waste to be co-digested with an efficient substrate in order to increase the amount of biogas produced is what is driving this research. Thus, the main objective of this research is to find the most efficient biogas production alternative by comparing the amount of biogas produced from cauliflower stems with cow dung using an affordable biodigester tank [12].

2. Materials and Methods

This experiment was carried out at the Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Chennai, India, in the Environmental lab of the Department of Biotechnology. For this experiment, two distinct samples were chosen: Group A consisted of 14 cauliflower stems, and Group B consisted of 14 cow dung samples. The following criteria were upheld when determining the sample size using a Clincalc: a 0.05 threshold, 80% G-power, 95% confidence interval, and a 1 enrollment ratio.

The stem of the cauliflower was gathered from Chennai, Tamil Nadu's Koyambedu market. A clean, covered container was used to gather fresh cow manure from a cow farm in Chennai. The cow dung was mashed with a mortar and pestle after it had dried for four days. The ground-up dung was sieved once more and dried again 0 (Sukasem, Khanthi, and Prayoonkham 2017).

The project uses cow dung and cauliflower stems as data. A biogas digester tank and biogas smart meter were built in order to generate biogas from both wastes. The produced biogas is collected in the gas holder, where a smart biogas meter measures the gas's flow and pressure during the methane conversion process. For each group over a 14-day period, Table 187.1 shows the volume of gas collected and the biogas pressure (measured in milliliters). A smart biogas meter is used to monitor the gas flow and pressure when the biogas is being released.

The garbage that was gathered was processed in a biodigester. Via the inlets of biodigesters 1 and 2, five kg of cow dung and cauliflower stem were introduced,

respectively. The pH range of 6.5 to 7 and temperature range of 30°C to 38°C of the biodigester's outflow pipe were connected to both the gas stove and the smart biogas meter. A smart biogas meter was used to measure the biogas that was produced.

2.1. Statistical analysis

Using SPSS version 21, a statistical study was conducted to compare the biogas output from cow dung and cauliflower stem. No dependent variables exist; biogas production is an independent variable. The Independent T-test, the Standard Deviation, and the Mean were all examined [1].

3. Results

As compared to cow dung (20.98 m³), Figure 187.1 illustrates that the highest amount of biogas produced by the cauliflower stem operating in a biodigester (12.45 m³) was less. Additionally, it was noted from Figure 187.1 that the biogas generated by using a biodigester with cauliflower stems increased quickly after one day and then progressively reached its maximum on the fourteenth day. Similar to this, the biogas generated from cow dung grew quickly at first, then more slowly until it peaked on the fourteenth day.

Additionally, a burning test was conducted, and the findings indicated that the maximum gas burning

Source: Author.

times for cow dung and cauliflower stems were 60 and 55 minutes, respectively.

Table 187.2 displays the findings of the statistical comparison between the cow dung and the cauliflower stem. The standard error and standard deviation for the cauliflower stem and cow dung were 5.32622 and 1.42349, respectively, and 5.78814 and 1.54695, respectively. Cow dung has a higher standard deviation than cauliflower stem; therefore, if combined with the right substrates, it has a higher chance of improving its digestive properties. It was possible to assess the biogas production processes utilizing cow dung and cauliflower stem by applying an independent T test (Table 187.3). There was a difference that was statistically significant (p < 0.05). It is clear from
Figure 187.2. Comparing the mean biogas generation of cow manure with cauliflower stems. While the standard deviation of cow dung is higher than that of cauliflower stem, the mean biogas output of cauliflower stem is much lower than that of cow dung. Cow dung vs. cauliflower stem on the X-Axis Biogas production on the Y-Axis is the mean ± 1 SD.

Source: Author.

Figure 187.2's comparison of the mean biogas output of cow dung and cauliflower stem that the latter produces noticeably more biogas than the former.

4. Discussion

The biogas output from the usage of cauliflower stem in an anaerobic digester in this study was about 12.45 m³ lower than that of the cow dung (20.9 m³), suggesting that the presence of easily digested materials in the cow dung may contribute to its ability to produce

biogas. In the burning test, the production of biogas from the cow dung and cauliflower stem started on the first day. The process's microbes were fully active from the time of construction until the first gas was produced. At this point, the gas for both wastes started to burn and methane production started. Nevertheless, because of the properties of its substrate, cauliflower stem demonstrated a shorter burning period at the conclusion of the experiments than did cow dung.

It was discovered that the waste from cauliflower contained 5.94% lignin, 9.12% hemicellulose, and 17.32% cellulose [2]. Waste cauliflower was dried at a temperature range of 60°C to 120°C [13] reported that a total methane output of 26.05 g/L was obtained after drying the cauliflower waste at 80°C. In their experimental investigation, Zhichao et al. [15] investigate the production of biogas in an anaerobic digester using a combination of cow dung and cauliflower stems. In a study conducted by, the anaerobic digestion of cauliflower stems combined with tea waste required 55 days to produce biogas [4, 7]. Experiment showed that the cauliflower stem and cow dung codigested in an equal ratio to produce biogas, and the retention period was observed to be 40 days [11] performed a study on the generation of biogas from cauliflower stem that was digested anaerobically at room temperature, and it was noted that the highest amount of biogas obtained was 15.60 m³ [1]. The larger digester, slurry, and gas collection device used in this study have contributed to increased gas production.

Waste-derived substrates are essential to the process of producing biogas. Consequently, selecting the right waste is seen to be one of the key elements in obtaining a high level of biogas production during the anaerobic digestion process. However, it is difficult to maximize the anaerobic digestion process due to the lack of nutrients and microbial communities. Additionally, there aren't any technologies accessible right now that can simplify, lower the cost of, and increase accessibility of the procedure. The government may decide to increase its investment in the biogas industry, which has the potential to rival the CNG market in the future, if the right ratio of appropriate substrates and additives is combined with innovative processes.

5. Conclusion

In comparison to cow dung (20.98 m³), this study demonstrates that cauliflower stems operated in biodigesters can produce 12.45 m³ of biogas, which is less than what cow dung can produce. All things considered, producing biogas from cow dung is a promising method that can help ensure a more economical and sustainable use of resources while offering a renewable energy source. For hotels and restaurants, biogas systems may be able to offset the expense of waste disposal with additional revenue.

188 Comparison of biogas production from the anaerobic treatment of corn starch waste with cow dung in the biodigester

S. Srija[1] and Baranitharan Ethiraj[2,a]

[1]Research Scholar, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
[2]Associate Professor, Research Guide, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: The primary goal aim this research is to contrast the amount of biogas produced in a biodigester by treating cow dung and corn starch waste anaerobically. Materials and methods: On the fourteenth day, the waste samples (cow dung and corn starch waste) were taken out of the biodigester. A smart biogas meter was used to calculate the biogas for both groups. A total sample size of 28 (α=0.05, 95% confidence interval, and 80% G power) was determined for the two groups, each of which had a sample size of 14. Result: The waste samples—cow dung and corn starch waste—were removed from the biodigester over the course of fourteen days. Biogas was found to have less corn starch waste (12.08 m^3) in the biodigester than cow manure (20.98 m^3). The findings showed that as compared to cow manure, the corn starch waste generated noticeably less biogas. With a p-value of 0.001 ($p<0.05$), independent t-test samples reveal a substantial difference between the two groups. This implies that the two groups differ statistically significantly from one another. Conclusion: The study suggests that a biodigester powered by cow dung could provide more biogas than one powered by maize starch waste.

Keywords: Food waste, energy, fossil fuel, agricultural waste, population, carbon dioxide

1. Introduction

The extensive use of these fossil fuels tends to increase emissions of carbon dioxide as a result of combustion and the cost of its production is very high. One of the ways to cope with the problems caused by fossils is to switch to an alternative resource that is cost-friendly and sustainable to the environment. The main objectives of anaerobic digestion is to break down the substrate by the action of bacteria to a valuable end product under anaerobic conditions. Numerous investigations on the generation of biogas from waste maize starch have been conducted recently. The production of biogas is largely dependent on the kind and quantity of waste material. Numerous investigations on the production of biogas from leftover maize starch have been conducted recently. Recently, a lot of research has been done on the creation of biogas from residual maize starch. You recently, a lot of research has been done on the creation of biogas from residual maize starch. In order to determine which waste is optimal for producing biogas digesters, the biogas production capacities of cow dung and corn starch waste were examined. This research aims to investigate the production of biogas from co-digested corn starch waste and cow dung in anaerobic bio digesters.

2. Resources and Techniques

The investigation was carried out at the Saveetha School of Engineering's Environmental Lab in the Department of Biotechnology in Chennai. This garbage was fed into the grinding machine, which turns the sample into tiny particles in preparation for processing at the biogas plant. The trash was gathered into a lidded, sterile container. A biogas digester tank and biogas smart meter were built in order to produce biogas from both sorts of garbage. The produced biogas is collected in

the gas holder, where a smart biogas meter measures the gas's flow and pressure during the methane conversion process. For each group over a 14-day period, Table 188.1 shows the volume of gas collected and the biogas pressure. A smart biogas meter is used to monitor the gas flow and pressure when the biogas is being released. The waste that was gathered was placed in a biodigester. Via the biodigester's input, 5 kilogram of waste corn starch and 5 kg of cow dung were supplied. A smart biogas meter was used to measure the biogas that was produced.

2.1. Statistical analysis

A statistical analysis was conducted to compare the production of biogas from corn starch waste and cow dung-operated biodigesters using SPSS version 21. Biogas generation is the independent variable; no other factors are reliant on it. Calculations were made for the independent t tests, standard deviation, and mean.

3. Results

The biodigester that utilized cow dung yielded higher biogas (20.98 m^3) than the one that used waste corn starch (12.08 m^3), as shown in Figure 188.1. According to Figure 188.1, biogas produced by the biodigester processing corn starch waste increased quickly

Source: Author.

after two days and peaked on the fourteenth day. In a similar vein, the biogas produced by the biodigester powered by cow dung first rose quickly before gradually increasing over the course of four days, peaking on the fourteenth day. Table 188.1 reveals that on the fourteenth day, cow dung created 20.98 m³ of biogas, whereas corn starch waste only managed to obtain 12.08 m³ of biogas.

In a burning test, the greatest burning times for gas derived from cow dung and cornstarch waste were 60 and 52 minutes, respectively.

Table 188.2 presents the results of the statistical analysis conducted on cow dung and corn starch waste. The results indicate that the former had a standard deviation of 3.29847 and a standard error of .88155, while the latter had a standard error of 1.54695 and a standard deviation of 5.78814. If mixed with suitable substrates, cow dung has a greater possibility to improve its digestive qualities than corn starch waste due to its larger standard variation. To compare the biogas generation powered by cow dung and corn starch waste, an independent T test was carried out. (Table 188.3) and a difference that was found to be statistically significant ($p = 0.050$). Figure 188.2 shows that the mean power density of the two types of waste—cow dung and corn starch waste—was significantly lower for the latter.

4. Discussion

This study found that a digester powered by cow dung generates more biogas than one powered by corn starch waste. Additionally, using SPSS version 21, a significant difference was found between the biodigester operated by cow dung and maize waste.

The biodigester that was operated using maize waste produced less biogas (12.08 m³) than the biogas

generated from cow dung (20.98 m³). This suggests that the corn starch waste has the capacity to produce biogas because it has an easily digested substrate [1, 6]. Comparable outcomes were seen when a biodigester powered by maize starch waste produced biogas. In this instance of the burning test, the gas output for the waste materials—corn starch and cow dung—was not revealed until the second day [13]. The process microorganisms were completely inactive during the setup and start gas generation phases. All of the oxygen in the digester was consumed during this period by the aerobic bacteria that were there. Gas generation started when the acid-forming bacteria turned active and consumed up all of the available oxygen 2021; Iweka et al. The amount of subtracts required for the second phase grew as fermentation progressed. (Wei and colleagues, 2022). Methane production started at this point, and the gas was burned for both waste and fuel. However, because of the properties of its substrate, corn starch waste had a longer burning period at the conclusion of the studies than did cow dung. (Hadiyarto, Pratiwi, and Septiyani 2019).

Research was done on different approaches to increase the generation of biogas. According to (Mohammed, Na, and Shimizu 2022), the kind and quantity of microbiological population in the digester will determine how much is produced. Waste corn starch is one of the greatest substrates for biogas production. Corn cobs, corn starch, maize straw, corn husk, and corn dung are the feed ingredients in the study [13], with different substrate materials. In contrast to previous approaches, it performs better. When compared to other wastes, cow dung has a larger volatile solid content and a higher concentration of biodegradable solids [15]. Even after multiple rounds of filtration, there are still a lot of contaminants in it that

are challenging to remove. According to the aforementioned study, using corn starch waste as a biodigester substrate has greater benefits than using cow manure.

The waste's constituents are essential to the production of biogas. Thus, selecting the right waste is seen to be one of the key elements in achieving high biogas generation during the anaerobic digestion process. However, because of nutritional imbalances and inadequate microbial populations, optimizing the anaerobic digestion process is difficult. Furthermore, there are currently no technologies available to streamline, lower the cost of, and increase accessibility of the procedure. In addition to the new approaches, an appropriate ratio of supplements and suitable substrates could encourage the government to invest more in the biogas business, making it competitive with the compressed natural gas market in the future.

5. Conclusion

This study demonstrates that, in comparison to biogas generated from maize waste, which produced 12.08 m^3, cow dung operated in a biodigester was able to reach a significant volume of biogas (20.98 m^3). This research confirms that cow dung produces biogas far more efficiently than maize waste. As a result, producing biogas is a viable strategy that can support the efficient and more sustainable use of resources while offering a substitute for fossil fuels as a renewable energy source.

189 Cr(VI) removal from simulated wastewater using HCl modified biochar of Wodyetia bifurcata seeds in comparison with commercial activated carbon

R. Yamini Loukya Indrani[1,a] and Saranya N.[2]

[1]Research Scholar, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Chennai, India
[2]Project Guide, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Chennai, India

Abstract: To determine the removal capacity of HCl modified biochar of *Wodyetia bifurcata* in removing Cr(VI) from simulated wastewater and comparing its results with the activated carbon of *Wodyetia bifurcata*. Materials and Methods: Cr(VI) stock solution of 1000mgL, HCl modified biochar was prepared for this study, 0.2 grams of 1,5 DPC in 100 ml acetone was used as a reagent for analysis purpose. The effects of concentration, pH, and time taken on the performance of the modified adsorbents were evaluated, and optimal conditions were determined. The objective of this study is to examine Cr(VI)'s adsorption capacities in three distinct contexts: pH, concentration, and time. With three factors comparing the two groups, the sample size is eight. It was determined that the G power value was 85%. Discussion: The rates of adsorption were also studied using statistical analysis under the optimal conditions with the various modified adsorbents. This study found that both modified and raw activated carbon (AC) were able to effectively remove Cr (VI) ions from aqueous solutions under certain treatment conditions Results: Specifically, the modified HCl form was able to remove 94% of the Cr(VI) ions at a dosage of 50 mg, a contact time of 3 hours, and a pH of 2, while the raw AC was able to remove 92% of the ions under the same conditions. At higher adsorbent dosages, the raw AC had a slightly higher removal efficiency, with 94.5% removal, compared to 94% for the modified AC with a significance of 0.994 (P>0.005). The adsorption capacity of HCl-modified biochar derived from *Wodyetia bifurcata* for chromium VI was 12.09 mg/g. Conclusion: The adsorption capacities of both types of AC were determined through batch adsorption experiments, and the experimental data was analyzed using statistical methods. Overall, the findings imply that, while modified AC has a little greater efficacy at lower dosages, both raw and modified AC can be useful in eliminating Cr (VI) ions from aqueous solutions.

Keywords: Wodyetia bifurcata, adsorption, aqueous, optimal conditions, dosage, efficiency, modified form, waste water

1. Introduction

In this study, we are evaluating the effectiveness of adsorbent, Wodyetia bifurcata for removing Cr through the adsorption technique. The type of carbon, the modification process, and other variables can all have a substantial impact on the effectiveness of chromium removal by adsorption utilizing activated carbons. This research involves testing the ability of an acid-modified form of the adsorbent Wodyetia bifurcata seeds to remove chromium VI. The genus name for this Australian species, The name Wodyetia is taken from the name of this individual, while the particular term "bifurcata" is Latin in origin and means "divided into two parts," referring to the forked fibers that surround the seeds. The potential of wodetia bifurcata seeds as an adsorbent material to remove pollutants from wastewater has not received much

research. It is possible that the fibrous outer layer of the seeds could have some adsorption properties, but more research would be needed to determine the effectiveness of Wodyetia bifurcata seeds as an adsorbent to remove contaminants from water. This study compares the results with activated form and looks at the adsorption capacity of activated Wodyetia bifurcata for chromium removal from a solution. The aim of this work is to explore the possibility of using Wodyetia bifurcata biochar treated with HCl as an adsorbent for the removal of chromium. The ideal settings for the removal process will be ascertained by assessing the activated Wodyetia bifurcata's adsorption capacity under a range of circumstances. The findings of this study could be applied to the creation of greener and more efficient processes for extracting chromium from industrial and other waste streams.

2.   Materials and Methods

2.1.   Setting up the Cr (VI) stock

Potassium dichromate was dissolved in deionized water to form a stock solution of 1000 mg/L, which was then used to create a working solution of chromium VI. The working solution was then made by diluting the stock solution to the required concentration.

2.2.   HCl modified biochar preparation

Wodyetia bifurcata fruits were collected from Saveetha School of Engineering Campus and the seeds were removed, washed thoroughly and dried. The seeds were activated in a muffle furnace at 300°C. The activated carbon was powdered and mixed with a mixture of 10% HCl solution of 100 mL. The resulting mixture was subjected to pyrolysis at a high temperature in an inert atmosphere resulting in the production of HCl modified biochar.

2.3.   Sample description

The sample size is calculated using a clinical tool. This research involved 8 samples divided into two groups [5]. Comparison between two groups is done by observing the following three parameters: pH, concentration and contact time. As per the researcher, ethical approval was not deemed necessary for this study.

2.4.   1,5 Diphenylcarbazide reagent preparation

0.2 grams of diphenylcarbazide was added to 100mL Acetone. Once it is completely dissolved, it is ready to use.

2.5.   Working procedure of DPC

By using a reducing agent, diphenylcarbazide lowers Cr (VI) to Cr (III) in the DPC technique. Chromium (VI) is reduced to chromium (III) with the aid of the reduction reaction, which is conducted in an acidic environment. The reaction between chromium (VI) and DPC.

In this instance, the DPC reduces the Cr (VI) to Cr (III), which is then oxidized to 1,5-diphenylcarbazone (DPCA). When chromium (III) complexes with DPCA in an acidic environment, a distinctive purple color is formed that indicates the presence of chromium (III).

2.6.   Adsorption studies of Cr(VI)

OD values of all samples are collected using a spectrophotometer at 540 nm, and concentration at any time is measured by using OD values. Removal percentage of chromium depends on the adsorption capacity of the adsorbent.

2.7.   Statistical analysis

Statistical significance of the study conducted SPSS (Statistical Package for the Social Sciences) version 26 was used for the analysis. For Chromium removal percentage by HCl modified form of *Wodyetia bifurcata* seeds and the activated form of *Wodyetia bifurcata* seed biochar. While pH and initial concentration are fixed dependent variables, time is the independent variable.

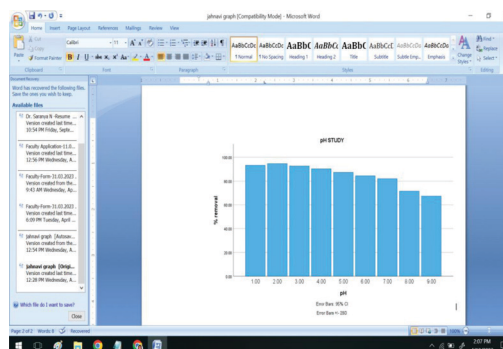
The percentage elimination of chromium VI exhibits statistical significance, as revealed by an independent sample test.


Figure. 189.1. Plotting the pH removal percentage of Cr(VI) for a range of pH values (1.0 to 8.0), the maximum removal percentage is seen at pH 2.0. According to reports, 94% of Cr VI elimination occurs at pH 2.0 with an X axis uncertainty of +/- 2. pH levels Y axis: percentage of Cr VI removed at various pH levels.

3.2. Concentration studies for the adsorption of hexavalent chromium

The study also discovered that the clearance % increased at a chromium VI concentration of 50 mg/L. This implies that the biochar that has been treated with HCl works best in acidic environments in Figure 189.4. Figure 189.3 shows that the clearance % increased when chromium VI was present at a concentration of 50 mg/L. It was discovered that Wodyetia bifurcata-derived HCl-modified biochar has an adsorption capability of 12.09 mg/g for chromium VI. This means that one gram of the modified biochar has the ability to adsorb 12.09 milligrams of chromium VI from a solution.

3.3. Time studies for the adsorption of hexavalent chromium

Overall, the study suggests that HCl-modified biochar could be a promising solution for removing chromium VI from contaminated water sources, particularly in acidic conditions. Figure 189.2, shows the information about the removal of chromium at different time intervals. The average time measured is 210 min. The elimination percentage rises with increasing time. There is a direct proportionality between time and removal percentage.

The high removal rate and enhanced performance at higher concentrations of chromium VI make this technology a potentially useful tool in addressing the problem of chromium VI contamination in the environment. Preparation of modified biochars is represented in Figure 189.5 and 189.6.

Tables 189.1 and 189.2 represented the mean, SD and probability of the experiments conducted with a sample size of 18 in 3 groups. The mean value for HCl_4-modified biochar was 76.80 and the same for commercially activated was found to be 76.90. The SD value was found to be 27.46 for HCl modified biochar and 27.39 for the activated biochar respectively. An independent sample t-test with an average of 16.0 degrees of freedom and a mean value of 0.994 was obtained by assuming equal and unequal variances. Table 189.3 represented a variance with 95% confidence interval.

4. Discussion

The efficiency of chromium removal was significantly higher in this study compared to previous research using activated form of *Wodyetia bifurcata* seeds, leading to the conclusion that the HCl modified biochar which is highly effective at removing chromium VI from wastewater.

In previous research studies, a removal efficiency of around 90 % for chromium has been reported by Activated biochar. On the other hand, this study's removal effectiveness was shown to be substantially higher, with about 94% of the chromium being eliminated. Biochar's removal capabilities were 87% in Penido E. S et al.'s 2021 study, and 92% in Wodyetia bifurcata's activated biochar. Table 189.1 displays the analysis's mean and standard deviation values, while Table 189.2 shows the results of the independent t-test carried out on the samples. The HCl-modified biochar's obtained standard deviation (27.46271) and standard error means (9.15424) are displayed in the table below. The standard deviation and standard error mean of activated carbon are 26.39530 and 9.13177, respectively.

It is important to be aware that DPC can have toxic effects and can cause serious health problems if inhaled, ingested, or absorbed through the skin. Therefore, caution should be exercised when using DPC in any situation, including in Chromium removal from wastewater. It is necessary to use proper protective measures when handling DPC and to carefully consider the potential health and environmental impacts of this chemical before using it.

Cr (III) can also be found in some food products, such as whole grains, nuts, and some types of meat, and is essential for human nutrition in small amounts. However, excessive exposure to Cr (III) can still be harmful and may cause skin irritation or allergic reactions; excessive intake can cause negative health effects.

5. Conclusion

This study shows that HCl modified biochar of *Wodyetia bifurcata* seeds is giving best results in removing Chromium VI from wastewater when compared to activated biochar without chemical modification which imply that acid modification intensified the process of anionic Cr(VI) adsorption onto HCl modified biochar. It was discovered that the outcomes lacked statistical significance. It is significant to remember that this study solely examined the efficacy of biochar treated with HCl in a lab setting. To assess its efficacy in practical applications and identify any potential downsides or restrictions, more study would be required.

Abstract: To disintegrate ammonium lauryl sulfate and comparative analysis of sonolysis against cetyl alcohol in an artificial aqueous media in a laboratory atmosphere were described. Materials and methods: Ammonium lauryl sulfate standard solution was freshly made, and its pH, time, and optimal temperature were all evaluated. The sample solution's initial concentration was determined to be 100 mg/L, with a pH range of 4 to 7. The solution's absorbance was measured with a UV-Vis spectrophotometer at a wavelength of 540 nm. Group 1 and group 2 of each 5 samples from each pH solution were collected for a numerical kind of analysis with the confidence interval 95%, G-power 80%, and enrollment ratio all set to one. Results: The temperature and pH have a big impact on how ammonium lauryl sulfate breaks down during sonolysis. At pH 8 and 80 C, ammonium lauryl sulfate breakdown accelerates. Ammonium lauryl sulfate had been shown to break down more quickly as pH, temperature, and suitable pressure were raised. Conclusion: In this analysis, the sonolysis breakdown of the ammonium lauryl sulfate chemical used in personal care products was conducted. The following measures had been shown in temperature, and a pH of 8 improves the effectiveness of ammonium lauryl sulfate breakdown.

Keywords: Wastewater treatment, ammonium lauryl sulfate, personal care products, advanced oxidation process, sonolysis

1. Introduction

Advanced oxidation processes were the process of chemical treatment which was designed to remove organic matter present in the waste water by oxidation through reactions with hydroxyl radicals (OH). Reactions between hydroxyl radicals and organic matter were exceptionally fast and non-specific [6]. AOPs were the most effective method which had the essential role in wastewater treatment of highly polluted toxic, nonbiodegradable organic compounds and hazardous pollutants [11].

A total of 87 review articles were located in the database science direct, which comprises roughly 312 research publications. Google Scholar contains over 68 research articles and nearly 182 review articles

for the study of sonolysis and its properties. A thorough examination of the research papers, studies, and reviews that have been published on this subject, its possible uses, and its methodologies was required for a review of the literature on sonolysis of ammonium lauryl sulfate. Advanced oxidation treatments, such as electrochemical oxidation, ultrasonication, and ionising, have successfully eliminated personal care products. In this study, information relevant to using advanced oxidation processes for eliminating personal care products from water and wastewater treatment systems was compiled from current studies on the subject [8]. Sonolysis, where it utilizes ultrasonic irradiation to break down water and liberate OH radicals, was one of the most used Advanced oxidation process

approaches. Nevertheless in order for the ultrasound-induced acoustic chamber of bubbles to work, energy was required [7]. Ultra sonicator was one of the process of Advanced oxidation processes. Sonication can be conducted using either an ultrasonic bath or an ultrasonic probe (sonicator). Ultrasonic frequencies (>20 kHz) are usually used, so the process was also known as ultrasonication [2].

In daily supplies, ammonium lauryl sulfate was one of the most popular detergents [4]. In usual personal care products including shampoos, body washes, and facial cleansers, ammonium lauryl sulfate was utilized as a surfactant. It was a lauryl sulfate salt that was manufactured from coconut oil. Ammonium lauryl sulfate was well regarded for its capacity to produce a thick lather and efficiently remove oil and debris from the skin, hair and wastewater. The aim of the study was focussed to examine the performance of sonolysis in degrading ammonium lauryl sulfate.

2. Materials and Methods

The study was carried out in a bioengineering laboratory in Saveetha School of Engineering, Chennai, India. Two groups were taken totally; each group carried 5 samples and the total sample size was 10 and this had been calculated based on [5]. The value of G power was determined to be 80% and the coincidence interval of 95% and the sample preparation was given below.

2.1. Ultrasonicator setup

Ammonium lauryl sulfate and distilled water were combined to create the sample. Because it becomes synthetic wastewater. When the synthetic wastewater sample's pH, temperature, colour, and turbidity have been assessed, it was then put into the ultrasonicator or sonolysis. Finally, when ultrasonic waves were applied to a liquid medium in a cycle of alternating high and low pressure, vacuum bubbles were created. When they grow and merge together, these bubbles finally reach a size where they collapse and cause a shock wave to travel through the mixture [11].

2.2. Quantitative analysis

The ultrasonicator's readings were recorded while it performed. At pH 4 and 7, the sample solution was prepared at an initial concentration of 100 mg/L, and monitoring was performed every 20 minutes. UV-Vis spectroscopy, also known as spectrometer, was used to calculate how much light a chemical substance absorbs. Following sonolysis, the sample solution's absorbance was measured using a UV-vis spectrophotometer with a 540 nm wavelength.

2.3. Statistical analysis

The mean, standard deviation, and standard deviation error of the findings were computed using IBM SPSS Version 26 software. One-way ANOVA analysis was used

to evaluate statistical significance p=0.001 (p<0.05). The independent parameters were pH 5 and pH 8 solutions that had been sonicated along with time and temperature.

3. Results

3.1. *Effects of temperature*

The breakdown of ammonium lauryl sulfate during sonolysis can be significantly influenced by the temperature. Because of increased molecular mobility and molecular collisions at higher temperatures, sonolysis typically occurs more quickly. Table 190.1. Includes the effect of varying pH and temperature in degradation of ammonium lauryl sulfate. Table 190.2 shows the effect of varying pH and time in breakdown of ammonium lauryl sulfate. Several temperatures were studied in order to look at how the reactions were affected by the operating temperature [3]. Figure 190.1 displays the outcomes of comparing the

chemical's phantolide elimination percentage under standard conditions at various temperatures and pH levels. Tables 190.3 and 190.4 shows the Comparison of the one way ANOVA test and multiple comparisons for varying temperature and pH shows the significant value of $p < 0.05$ using SPSS Analysis of chemical compound ammonium lauryl sulfate.

3.2. Effects of pH

The efficiency with which sonolysis, which employs sound waves to break down the ammonium lauryl sulfate molecules, works can be greatly influenced by the pH of the solution. Also, in an alkaline environment, the anionic form of the chemical facilitates the absorption of more hydroxyl ions by ultrasonic waves and the subsequent creation of more hydroxyl radicals, increasing the ammonium lauryl sulfate's ability to degrade.

The influence of pH value could be understood to mean that all types of organic components in wastewater as well as ammonium lauryl sulfate were affected by pH value. Since it was generally known that pH value can impact a substance's physicochemical characteristics in an aqueous solution, it was logical to assume that pH value can also affect a substance's rate of ultrasonic breakdown. In general, ammonium lauryl sulfate was water soluble [9]. The resultant solutions have pH values below 7.0 and include moderate amounts of hydrogen ions.

Figure 190.2 displays the outcomes of comparing the chemical's phantolide elimination percentage under standard conditions at various time and pH levels. Tables 190.5 and 190.6 represents the Comparison of the one way ANOVA test and multiple comparisons for varying time and pH shows the significant value of $p < 0.05$ using SPSS Analysis of chemical compound ammonium lauryl sulfate. The pH of the sample solution was between 5 and 8 at various levels. Since, the lack of a perceptible improvement in ammonium lauryl sulfate elimination had caused the pH level to increase even further. Ammonium lauryl sulfate degradation efficiency was unexpectedly low as long as the environment remains acidic. As pH increased breakdown efficiency also increased [3].

4. Discussion

The results and tested values from the analyses that were looked at were shown in Tables 190.1 and 190.2. The results of comparing the normal breakdown of the chemical's phantolide elimination percentage at various temperatures and pH levels were shown in Figure 190.1. It was clear that ammonium lauryl sulfate does not have an initial degradation percentage that was successful, but when temperature and pH

rise, the degradation percentage continuously rises. The percentage of chemical component elimination increases as pH was gradually raised over a period of time. Figure 190.3 contrasts between ammonium lauryl sulfate and cetyl alcohol with the rising temperature. Ammonium lauryl sulfate was broken down at a pH of 8 and a temperature of 70 C, so its degradation was more effective than cetyl alcohol was when compared to it. Limitations: Ammonium lauryl sulfate can be rough on the surface of the skin. Ammonium lauryl sulfate can dry out the scalp and hair, which can result in problems like dandruff and breakage. Future scope: Due to its slow rate of biodegradation, ammonium lauryl sulfate had the potential to linger in the environment and pollute water. Its efficacy can be increased by employing it as a pre-treatment technique, and it can assist in lowering the environmental impact of the production of personal care products.

5. Conclusion

The sonolysis breakdown of the ammonium lauryl sulfate ingredient used in personal care products was tested in this analysis. Tests were carried out and assessed the impact of several process factors including beginning concentration, pH, time, and temperature. The initial ammonium lauryl sulfate concentration was found to be a factor in the reaction rate. At temperature (>70°C), pH (8), the efficacy breakdown of ammonium lauryl sulfate was increased. Analyzing statistical significance value $p = 0.001$ ($p < 0.05$) involved using a ONE WAY ANOVA test. The results of the research have demonstrated that it was theoretically possible to sonolysis an ammonium lauryl sulfate molecule. It had the potential to be a really helpful solution for extensive water treatment.

Abstract: To estimate the performance of cetyl alcohol sonolytic degradation. Materials and methods: By combining distilled water and cetyl alcohol, a chemical solution with a pH between 4.4 and 7 was obtained. Five separate time intervals were taken, results were recorded, and pH ranges between 4.4 and 7 were set down in a table for every 10 minutes. For each pH solution, two groups of five samples were taken, and using IBM SPSS Version 26, a one-way Anova test was run to compare the samples using a numerical type of analysis with the enrollment ratio, G-power, and confidence interval all set to one (N=10). Results: A freshly prepared test solution of cetyl alcohol was evaluated at various pH levels and suitable temperatures. The outcomes were recorded and assessed. The pH range considered was 4.4 to 7, and the sample solution's starting concentration was set at 100 mg/L. A UV-Vis spectrophotometer was used to determine the solution's absorbance at 560 nm. For statistical observation, the mean-variance was compared between Group 1 and Group 2 using a one way An analysis of variance test yields a significance value of $p=0.001$ ($p<0.05$). Conclusion: The effectiveness of removal and the frequency of response during the sonolysis process may both be impacted by temperature. A pH and temperature were indeed two of the factors that affect how effectively cetyl alcohol can be taken down by sonolysis. For the breakdown of cetyl alcohol, sonolysis operates efficiently.

Keywords: Sonolysis, advanced oxidation process, cetyl alcohol, wastewater treatment, personal care products

1. Introduction

In the database science direct it had about 275 research articles, 58 review articles were found to carry out the experiments. A literature review on sonolysis of Cetyl alcohol would involve a comprehensive analysis of published research articles, studies and reviews on this topic its applications and its methods. In google scholar nearly 140 review articles were present and about 760 research articles were present for the study of the sonolysis and their features. This was because contaminants were oxidized in the presence of ultrasound when OH radicals were produced in aqueous solutions. Thermal dissociation of the solvent and gas molecules present in the bubble at the time of transient collapse was the mechanism through which radicals were produced in sonolysis. Over the past 200 years, greater cleanliness had contributed to a twofold increase in life expectancy and a significant decrease in infectious diseases. A number of these, along with some minor changes within populations, may be brought on, at least partially, by the use of personal hygiene products and other environmental pollutants. Cetyl alcohol had a low toxicity and was typically regarded as safe for usage in cosmetics and personal care products. Cetyl Alcohol serves as an emulsifier, an

emollient, a soothing lubricant, a thickening, an opacifier, a carrier for other substances in a composition, and all of these functions when it was added to natural cosmetic preparations. The completed product had an effortless glide on the skin or hair thanks to these stabilising characteristics, which guarantee that the oils and water remain mixed.

2. Resources and Techniques

The Saveetha School of Engineering in Chennai, India, has a bioengineering lab where the study was conducted. Two groups were taken totally; each group carried 5 samples and the total sample size was 10 and this had been calculated based on [5]. The value of G power was determined to be 80% and the coincidence interval of 95% and the sample preparation was given below.

Cetyl alcohol was mixed with distilled water. It was called synthetic distilled water. In the process known as sonochemistry, ultrasonic waves were utilized to cause chemical or physical changes in a solution. When it comes to cetyl alcohol, sonochemistry can be employed to cause the molecules to break down into smaller pieces. High-frequency sound waves were used to create small bubbles in a solution in sonochemistry, which causes them to form and burst. When these bubbles burst, significant temperatures and pressures were produced, which can cause chemical reactions in the solution. This process was called cavitation.

2.1. Quantitative analysis

The absorbance of the solution at 560 nm was measured with a UV-Vis spectrophotometer. UV-Vis spectroscopy is a quantitative technique that quantifies the amount of specific UV or visible light wavelengths absorbed by or transmitted through a sample relative to a standard or blank sample.

2.2. Analytical statistics

The mean, standard deviation, and standard deviation error were estimated using the IBM SPSS Software Version 26 application. Using a ONE WAY ANOVA test, the statistical significance $p=0.001$ ($p<0.05$) was analyzed, Sonicated pH 4.4 and pH 7 solutions with time and temperature were the independent parameters.

3. Results

3.1. Effects of temperature

Several variables may affect the precise temperature needed to degrade cetyl alcohol in an ultrasonic bath. Typically, chemical elimination rises along with temperature rise. As a result, cetyl alcohol removal efficiency rises. A range of temperatures from 30°C to 70°C were selected and tested to determine how effectively the cetyl alcohol was removed [3]. Table 191.1 it involves the comparison of effects of varying pH and time in demineralizing cetyl alcohol compounds. Table 191.2. Shows the comparison of the effect of varying

pH and temperature in demineralizing cetyl alcohol compound. Tables 191.3 and 191.4. It shows the comparison of the one way ANOVA test for varying temperature and pH shows the significant value $p < 0.05$ using SPSS analysis. Figure 191.1 shows the outcome of comparing the typical breakdown of cetyl alcohol at various temperature and pH levels.

3.2. Effects of pH

It had been observed that the pH levels of the sonicated cetyl alcohol were 4.4 and 7, respectively. Cetyl alcohol and other types of organic components were disseminated in the wastewater in different ways, according to the pH value's effect, which can be interpreted as having an impact on this. It was well-known that a substance's pH level can have an impact on its physicochemical properties. Cetyl alcohol can be removed more effectively when the pH rises [3]. Tables 191.5 and 191.6. Shows the comparison of the one way ANOVA test for varying time and pH shows the significant value of $p < 0.05$ using SPSS analysis. Figure 191.2 comparison of mean amount of degradation rate of cetyl alcohol solution at regular intervals of time.

4. Discussion

Sonolysis was used to treat wastewater from the personal care products industry, according to the research provided in this publication. Sonolysis, or the use of ultrasonic waves, was a simple technology that explored interesting applications in the hunt for more efficient and environmentally friendly processes. Tables 191.1 and 191.2 include the findings and tested values from the studies that were evaluated [4].

Figure 191.1 shows the outcome of comparing the typical breakdown of cetyl alcohol removal percentage at various temperature and pH levels. It was evident that cetyl alcohol does not initially have an effective removal percentage, but that percentage steadily increases as temperature and pH rise. Considering the average degree of deterioration over [9].

The discussion could involve the occurrence and behavior of cetyl alcohol in wastewater, including its sources, concentrations, and fate during different stages of wastewater treatment processes. This could include information on the potential for cetyl alcohol to enter wastewater streams from various sources, such as industrial discharges or domestic effluents, and its behavior during primary, secondary, and tertiary treatment processes, including its potential for removal through physical, chemical, or biological processes [6].

A comparative analysis had been performed to determine when temperature disrupts solutions. In Figure 191.3, cetyl alcohol and sodium laureth sulfate,

respectively, were contrasted with a pH 7 environment. The rate at which substances degrade often increases with warmth. When compared to cetyl alcohol, the efficacy of the breakdown of sodium laureth sulfate increased since it can be broken down at a pH of 7 and a temperature of 70°C.

Limitations: Like many other substances, cetyl alcohol might irritate some people's skin. Redness, itching, and pain are possible side effects, particularly in people with sensitive skin or pre-existing skin disorders. It is crucial to conduct a patch test on a small section of skin prior to applying products containing cetyl alcohol to bigger body parts. Although cetyl alcohol was generally considered safe for most people, some individuals may be allergic to cetyl alcohol. Allergy symptoms might include rash, hives, swelling, and trouble breathing. They can also differ in severity. If you suspect an allergic reaction to cetyl alcohol, discontinue use and seek medical attention.

Future scope: Sonolysis, also known as ultrasonic degradation or ultrasonic treatment, was a process that involves the use of high-frequency sound waves to induce physical, chemical, and biological changes in a liquid medium. Because sonolysis has the ability to accelerate the breakdown of contaminants and raise the general efficacy of wastewater treatment procedures, it has been researched and used in a number of fields, including wastewater treatment.

5. Conclusion

Pharmaceuticals and personal care products were currently the typical toxins that play a key role in wastewater treatment. The challenge of properly treating wastewater discharge from the chemical and process industries had been tackled by processing engineers and environmental organizations. The ability of sonolysis to break down cetyl alcohol depends on a number of variables, including pH and temperature (70°C). The degree to which cetyl alcohol was degraded can be affected by the solubility, stability, and reactivity of the chemical, all of which can be affected by the pH 7 of the solution. It was a method that had been employed frequently to degrade the organic matter contaminants in water. Temperature can affect the sonolysis process' response rate, which could potentially have an effect on how well substances were removed. Using a ONE WAY ANOVA test, the statistical significance $p=0.001$ ($p<0.05$) was analyzed.

Abstract: To produce biobutanol from pre-treated *Syzygium cumini* biomass and compare it with sugarcane straw. Materials and methods: In this investigation, *Syzygium cumini* leaves were collected, dried, ground into a fine powder, and subjected to hydrothermal processing. The resulting sample was subsequently treated with diluted sulfuric acid via acid hydrolysis to produce the required amount of sugar, which was then fermented with *C. acetobutylicum* to produce biobutanol. The study was conducted using two distinct groups of seven samples each, with a G power of 80% and coincidence intervals of 95%. Results: The study's findings suggest that *Syzygium cumini* could be utilized as an effective substrate for biobutanol production, with a yield of 5.4 g/L under optimal conditions. Furthermore, the two-tailed t-test analysis yielded a statistically significant p-value of 0.04 (p<0.05) for the independent variable. Conclusion: The utilization of lignocellulosic biomass as a substrate for biobutanol production presents a promising avenue to enhance the efficiency of the ABE fermentation process.

Keywords: Acid hydrolysis, biobutanol, hydrothermal pretreatment, lignocellulosic biomass, novel microorganism, production, syzygium cumini

1. Introduction

The global crisis included the volatility of petrol prices and the depletion of the oil supply as a result of the burning of fossil fuels for energy production. Two-thirds of the butanol and one-tenth of the acetone produced in the United States in 1945 came from ABE fermentation systems. One of the main goals of study was to make the manufacturing of biofuels feasible. Genetic engineering, applied microbiology, and process and bioprocess technologies breakthroughs and improvements may increase the economic competitiveness of the fermentation pathway for the production of biobutanol. This led to the use of fuel butanol in combustion engines as a substitute source of fuel. Biobutanol produced from C. butylacetonicum N1-4 had received about 83 citations and confirmed the importance of ABE fermentation. In order to enhance the production of biobutanol from renewable biomass, this paper reviewed the bioprocessing technologies and applicable methodologies that had been used was the most cited article with 72 citations. The study was under phenolic aldehydes stress, the final butanol and total solvent titers were 6. Thus, ABE fermentation might be a workable method for the production of biobutanol and that the existing use of bioethanol and biodiesel was insufficient to fulfill the rising need for biofuels. It might be produced through the fermentation of acetone, butanol, and ethanol [11].

2. Materials and Methods

The current study was carried out at the bioengineering laboratory of Saveetha School of Engineering. This investigation included a sample size of 14, which was divided into two groups of seven samples each as suggested by [9]. The sample size was calculated based on [3] with a power of 80% and a confidence interval of 95%. The categorization of the groups was based on the optimization of various factors, including

the concentration of acid and the duration of acid hydrolysis.

2.1. *Sample collection*

The raw material used in this study was lignocellulosic biomass of *Syzygium cumnini* which was collected from agricultural farms. The raw material was dried at room temperature and then it was milled to a fine powder. The biomass was then sieved and stored in an airtight container.

2.2. *Microorganism and growth condition*

The bacteria *C. acetobutylicum* MTCC11274 was acquired from the MTCC (Microbial Type Culture Collection) from Chandigarh, India. The culture was then maintained in anaerobic conditions. For spore activation, 200 mL of distilled water was mixed with 7.5 g of reinforced Clostridial medium (RCM) before the mixture was autoclaved for 15 minutes at 121°C. About 0.5 N NaOH was used to bring the pH down to 6.8. A 100 mL anaerobic, airtight glass container was filled with almost 80 mL of reinforced *Clostridial* broth medium, which was then inoculated with spores and cultured at 37°C for 72 hours [16].

2.3. *Hydrothermal pretreatment of* **Syzygium cumini**

This pretreatment method was performed in a 5L stainless reactor, 20 g of milled biomass and 20 mL of distilled water in (1:10) ratio were taken in a 250 mL conical flask then the system was heated up for 170°C–200°C up to 45 mins. After the process the sample was cooled down at 40°C, then by filtration the solid and liquid fractions were separated [13].

2.4. *Acid hydrolysis*

Acid hydrolysis of pretreated biomass was performed in a 250 mL conical flask. Dilute sulfuric acid was used for the hydrolysis. Precisely 1%-4% of dilute sulfuric acid was inoculated in 10 mL of hydrothermally pretreated biomass and then it was autoclaved at 121°C for 40 mins [11].

2.5. *Parameters optimization*

All experiments were performed in 250 mL conical flasks and the effects of sulfuric acid concentrations ranging from 1% to 4% in 10 mL of pretreated biomass were examined during acid hydrolysis. Hydrothermally pretreated biomass was used to perform acid hydrolysis for a period of time ranging from 10 to 40 min.

2.6. *Fermentation process*

This experiment was performed in a 250 mL conical flask; there were totally two groups and each group contains 7 conical flasks. Each conical flask was filled with 20 mL pretreated hydrolysate, 0.06 g of peptone and 0.02 g of yeast extract and it was sealed rubber cork then it was autoclaved at 120°C for 15 mins, using 5M NaOH, the pH was adjusted to 6.8. Following the procedure, the conical flask was cooled to room temperature and then purged for five minutes with pure nitrogen to obtain anaerobic condition. It was inoculated with 3mL growing culture and incubated at 37°C for 72 h. Throughout the fermentation liquid samples were taken every 6 h and examined [15].

2.7. *Analytical method*

Characterization of unpretreated and pretreated biomass was performed in FTIR- 4200 (Fourier Transform Infrared) spectroscopy (Jasco Japan) presented by Indian Institute of Technology Chennai. The optical density at 660 nm of the culture was measured with an U1000 spectrophotometer. The cell-free culture media was used as a control when determining the optical densities of the cultures and the cell's dry weight was computed. High performance liquid chromatography (HPLC) was used to quantify butanol produced.

2.8. *Statistical analysis*

The IBM SPSS Software Version 26 application was used to calculate results such as mean, standard deviation and standard deviation error. The dependent variable was concentration in acid hydrolysis and time in acid hydrolysis and the independent variable was not used in this study [4]. Two tailed T-tests was applied to examine statistical significance using SPSS software.

3.2. Hydrothermal pretreatment and acid hydrolysis

This experiment was carried out in 250 mL conical flask and hydrothermal pretreatment was performed to break down the lignocellulosic compounds. About 20 g of dried biomass was dissolved in 200 mL of distilled water and then heat was heated up to 170°C-200°C for 45 min. In this stage lignocellulosic biomass was broken down into cellulose, hemicellulose and lignin. Afterwards, acid hydrolysis was performed for further breakdown of cellulose, hemicellulose and lignin. About 2% (w/v) dilute sulfuric acid was added to the pretreated substance. This mixture was incubated at room temperature for 20 min. The presence of cellulose and hemicelluose in *Syzygium cumini* biomass was shown in Figure 192.2.

3.3. Growth of microorganisms

Microbial species of *Clostridium acetobutylicum* MTCC 11274 bacteria was cultured in growth media that had been made in accordance with IMTECH Chandigarh instructions. After 12–16 hours, cell growth was found to be increased and reached the stationary phase after 40 h as shown in Figure 192.3.

3.4. Optimization of biomass pretreatment

The effect of acid concentration on the pretreatment was investigated. The maximum sugar yield was obtained at 3.5% of H2SO4 concentration and low level of sugar yield was recorded at 2.5% of acid concentration as shown in Figure 192.4. The effect of time on the pretreatment of biomass was investigated and the maximum sugar yield was obtained at 35 mins

as shown in Figure 192.5. Further increase in time reduced the sugar yield from biomass.

3.5. *Fermentation method*

The hydrothermally pretreated Syzygium cumini was used to produce butanol by using Clostridium acetobutylicum at 37oC. As shown in Figure 192.6, the maximum butanol was obtained at 72h with a production of 5.4 g/L and minimum butanol was obtained at 6 h with a production of 0.3 g/L. At 12 h the production of biobutanol was similar to butanol produced at 18 h.

3.6. *Statistical analysis*

The IBM SPSS Software Version 26 application was used to calculate results such as mean, standard deviation and standard deviation error. The dependent variable was concentration in acid hydrolysis and time in acid hydrolysis and the independent variable was total sugar yield. Table 192.1 represents the mean, standard deviation and standard error comparison of effect of time and concentration during hydrolysis. When comparing the Independent sample T test values between groups reveals the significant value with p value of 0.04 ($p < 0.05$) as shown in Table 192.2.

4. Discussion

This study implemented hydrothermal pretreatment and acid hydrolysis to convert lignocellulosic biomass into simple sugar and which was subsequently used for biobutanol production by *Clostridium acetobutylicum*. The sugar yield was determined to be reliant on the concentration and duration of acid hydrolysis. The highest butanol production of 5.4 g/L was achieved after 72 h of fermentation at 37°C. These results indicated that *Syzygium cumini* lignocellulosic biomass, treated with hydrothermal pretreatment, has the potential to be utilized for biobutanol production.

Liquid hot water pretreatment of sugarcane straw was reported for ABE fermentation utilizing two distinct approaches: SHF (Separated Hydrolysis and ABE Fermentation) and PSSF (Pre Saccharification, Simultaneous Saccharification and ABE Fermentation) at varying biomass loading rates [9]. The SHF method included enzymatic hydrolysis of 100 g pretreated biomass in 1 L of distilled water at 50°C for 24 hours, followed by ABE fermentation for 96 hours, resulting in a biobutanol yield of 6.8 g/L. Meanwhile, in the PSSF approach, the pretreatment biomass was enzymatically hydrolyzed for 24 hours at 50°C before being fermented for 96 hours. The results shown in Figure 192.7 biobutanol production was greater in *Syzygium cumini* biomass compared to sugarcane straw substrate in this study.

4.1. *Future scopes and limitations*

However, the development of biobutanol as an alternative to fossil fuels faces several limitations, such as lower yield rates, limited availability of appropriate feedstocks, and recovery process difficulties. Despite these challenges, this study presents promising results for biobutanol production from *Syzygium cumnini* using hydrothermal pretreatment and acid hydrolysis techniques with optimized parameters. These advancements suggest that biobutanol production could be a highly efficient means of generating alternative fuel sources in the future.

5. Conclusion

The findings of this study demonstrate notable biobutanol production from pretreated *Syzygium cumini* biomass and compared to prior research on biobutanol production from sugarcane bagasse. The application of hydrothermal pretreatment and acid hydrolysis techniques, coupled with optimized parameters, resulted in enhanced microorganism growth during ABE fermentation. As a consequence of these advancements, the produced biobutanol exhibits significant potential as an effective and efficient means of biobutanol production in the coming years.

193 Comparison of biogas production from the anaerobic treatment of animal waste with cow dung in the biodigester

Mohammed Ismail sharieff[1,a] and Baranitharan Ethiraj[2]

[1]Research Scholar, Department of Biomedical Engineering, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

[2]Associate Professor, Research Guide, Department of Biotechnology, Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract: This study compares the amount of biogas produced by the anaerobic digestion of animal waste in a biodigester using cow dung. Materials and Methods: The waste samples—cow dung and animal waste—were removed from the biodigester on the fourteenth day. For both groups, biogas levels were determined via a smart biogas meter. The sample size was determined to be 28 ($\alpha=0.05$, 95% confidence interval, and 80% G power) with two groups, each having a sample size of 14. Results: 14 days of 80% G power operation were required for the waste samples taken from the biodigester containing 14 animal waste samples and 14 cow dung samples. Compared to cow dung (20.98 m^3), it was discovered that the biogas produced in the biodigester had a higher amount of animal waste (29.68 m^3). The findings showed that when compared to cow dung, animal waste generated noticeably more biogas. The results of the independent sample t-test show that the difference between the two groups is statistically significant, with a p-value of 0.048 ($p<0.05$). Conclusion: This research shown that using animal waste in a biodigester can provide more biogas than using cow dung.

Keywords: Animal waste, biogas, cow dung, energy, biodigester, anaerobic digestion

1. Introduction

There is an increasing demand for energy to meet the demands of an expanding global population. Nonetheless, there are growing worries regarding the depletion of non-renewable fossil fuels like coal, oil, and gas as well as unfavorable environmental effects like global warming because of our heavy reliance on them. It is necessary to find new energy sources to address these problems. One option is the anaerobic digestion of organic and inorganic waste, which produces biogas, a form of biofuel. Anaerobic digestion involves microbial waste decomposition without oxygen, generating biogas [4, 5]. In general, biogas can help with both environmental problems and the growing demand for electricity. When specific bacteria decompose organic material in anaerobic settings, a Green Energy source known as biogas is produced. It contains carbon dioxide, methane, and hydrogen. Anaerobic digestion is the biological breakdown of biodegradable material by microbes without the need of oxygen. Livestock manure, which contains organic waste, is one of the main feedstocks used in the biogas manufacturing process. Biogas can be used for a variety of thermal applications, including heating, lighting, and power generation. It can also be used to generate heat for cooking and other applications. Additionally, biogas can help reduce waste by replacing Liquefied Petroleum Gas (LPG) cylinders, which are frequently used in the hospital and culinary industries [10].

In an anaerobic digestion tank, biodegradable waste such as food waste, agricultural waste, and vegetable waste breaks down into a mixture of gases known as biogas. For the creation of biogas, the kind of animal waste—cow dung, poultry, chicken litter, pig manure, etc.—is crucial [1]. In a regional network of manure providers and biogas producers, the study by Bayar-saikhan, Ruhl, and Jekel [2] detailed the necessity of

employing animal dung to manufacture biogas and an alternative fertilizer. In this study, the key variables affecting biogas production will be determined. The capacity of cow manure to generate biogas was investigated by [8]. The methane concentration recorded was 47% and the average cumulative biogas generation was 0.15 L/kg VS added. Biogas generation frequently occurs in mesophilic settings when it is used to produce stable animal manure for use as fertilizer in large-scale anaerobic digestion plants as well as residential fuel. According to a 2019 article by [9] organic waste from farms and slaughterhouses has the potential to be converted into biogas. They also reported that animal waste has the capacity to produce 4589.49 million m³ of biogas each year.

A significant amount of biogas might be produced from the waste that is now being utilized to make biogas. Improved biogas generation requires the identification of more efficient waste resources.

2. Resources and Techniques

The Environmental Lab of the Department of Biotechnology at the Saveetha School of Engineering, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India, was the site of this investigation. Ethical approval is not required for this experiment because no human samples are used. For this experiment, two distinct samples were chosen: Group A consisted of animal waste (n = 14 samples); Group B consisted of cow dung (n = 14 samples). Based on a Clincalc observation, the sample size was examined with a 0.05 threshold, 80% G-power, 95% confidence interval, and 1:1 enrollment ratio. The animal feces was gathered at Kanchipuram, Tamil Nadu's B.S.A. poultry and fish market. Using a mortar and pestle, the animal manure was properly combined and ground up. From a cow farm near Chennai, fresh cow excrement was gathered. The garbage was collected in a sanitized container with a lid. Cow dung was ground with a mortar and pestle, sieved, and then dried once more. Four days were spent in the sun drying the cow manure [7]. This experiment uses cow poo and animal waste as its dataset. A biogas digester tank and biogas smart meter were built in order to produce biogas from both sorts of garbage. The produced biogas is collected in the gas holder, where a smart biogas meter measures the gas's flow and pressure during the methane

conversion process. For each group over a 14-day period, Table 193.1 shows the volume of gas collected and the biogas pressure (measured in milliliters). A smart biogas meter is used to monitor the gas flow and pressure when the biogas is being released.

The waste that was gathered was stored in a biodigester. 5 kg of animal waste and 5 kg of cow dung were added through the corresponding inlets of biodigesters 1 and 2. The gas holding was connected to the outflow pipe of the biodigesters (pH: 6.5–7, temperature: 30–36°C), which was connected to the smart biogas meter and the gas stove. A smart biogas meter was used to measure the biogas that was produced.

3. Statistical Analysis

Using SPSS version 21, a statistical study was carried out to compare the production of biogas from cow dung and animal waste. In this study, the production of biogas is the independent variable; there are no dependent factors. The independent t-test, mean, and standard deviation were all analyzed.

Table 193.1. Comparison of the data value accuracy for biogas produced by a biodigester using cow dung and animal waste. 28 samples in all, 14 samples each sample

Figure 193.1. This graph shows the biogas production of cow dung and animal waste 14 days results. By observing the graph, we can clearly denote the difference between cow dung and animal waste biogas production. More biogas is produced by animal waste than by cow dung.

Source: Author.

Figure 193.2. Comparing the average biogas output from cow dung and animal waste. Compared to animal waste, cow dung produces substantially more biogas on average, while animal waste has a lower standard deviation. X-Axis: Cow dung vs. Animal Waste Y-Axis: Mean biogas generation ± 1 SD.

Source: Author.

4. Results

Table 193.1 showed that the amount of biogas produced by an animal waste-operated biodigester (29.68 m³) was greater than that of cow dung (20.98 m³). Figure 193.1 showed that the biodigester powered by animal feces increased its biogas production quickly after two days, reaching its maximum on the fourteenth day. Similar to this, the amount of biogas generated from cow dung climbed quickly at first, then more gradually, reaching its peak on the fourteenth day.

The greatest burning time of gas from cow dung and animal waste, according to a burning test, was 60 minutes and 72 minutes, respectively.

The results of the statistical comparison between cow dung and animal waste are displayed in Table 193.2, where the standard deviations for each are 9.15273 and 2.44617 for animal waste, and 5.78814 and 1. 54695

for cow dung. Animal waste has a bigger standard deviation than Cow dung, which increases the likelihood that it will improve the digestive characteristics if combined with the appropriate co-substrates. An independent T-test was performed to see if there was a statistically significant difference between the animal waste and cow dung utilized in the biogas generating process. With a 2-tailed value of p=0.048, Table 193.3 showed a significant difference (p<0.05) between the two groups. It is clear from Figure 193.2's comparisons of the mean biogas production from cow dung and animal waste that the former produces more biogas than the latter.

5. Discussion

This study verified that, in comparison to a digester that uses cow dung, one that uses animal waste bio-operated in the digestion yields more biogas. Using

SPSS version 2.1, it has also been noted that there are notable distinctions between digesters that run on animal waste and ones that run on cow dung. The animal waste produced significantly more biogas than the cow dung, as evidenced by the biodigester's ability to reach a pressure of approximately 29.68 m³ as opposed to 20.98 m³.

Regarding the burning test, the production of gas for both the animal and cow dung did not begin until the second day. The microorganisms in charge of the procedure were completely dormant between setup and the first gas generation. All the oxygen in the digester was being consumed at this time by the aerobic bacteria. Once all of the oxygen had been used, the bacteria that produce acid became active and gas production began. However, the majority of this first gas was carbon dioxide. More of the subtracts required for the second phase were created as the fermentation progressed. At this point, the gas for both wastes began to burn and the process of producing methane began. At the conclusion of the trials, however, animal waste had a longer burning time than cow dung because of the properties of its substrate. Animal waste outperforms cow manure when it comes to biogas production. The number of animal husbandries in India has increased significantly in recent years. A 2011 study by Castrillón et al. found that rumen material, blood, and dung are among the many waste products produced by animals. This garbage is a great resource for biogas production. In addition to producing slurry, this can be burned for slaughterhouse, agricultural, and residential uses. A sizable amount of the slurry produced by the biodigester, which was used to create biogas from animal waste, is used as premium agricultural fertilizer because of its high concentration of organic components. By diluting the concentrated slurry with water in a 1:1 ratio, it can be used to treat fields before planting.

Waste-derived substrates are essential to the process of producing biogas. Consequently, selecting the right waste is seen to be one of the key elements in achieving high biogas generation during the anaerobic digestion process. However, because of nutritional imbalances and inadequate microbial populations, optimizing the anaerobic digestion process is challenging. Furthermore, there are currently no technologies available to streamline, lower the cost of, and increase accessibility of the procedure. In addition to the new approaches, an appropriate ratio of supplements and suitable substrates could encourage the government to invest more in the biogas business, making it competitive with the compressed natural gas market in the future.

6. Conclusion

This study demonstrates that, in comparison to cow dung (20.98 m³), an animal waste-operated biodigester may produce more biogas, with a value of 29.68 m3. All things considered, the creation of biogas from animal waste is a viable strategy that can help ensure a more economical and sustainable use of resources while offering a renewable energy source. Businesses could be able to generate income from the expense of waste management by implementing biogas systems.

Abstract: In order to accelerate combustion, 3:2 rice husk was added as a binder to sawdust from Azadirachta indica, and the heating performance of these briquettes was examined in this study. Resources and Techniques: The heating value, moisture %, volatile percentage, ash percentage, and fixed carbon value are all determined in this study. Using clinicalc.com, the sample size was determined with N=18 for each group based on the literature that was available, a 0.05 alpha error-threshold, a 95% confidence interval, and an 80% G power. Result: The results show that the sawdust-bound rice husk briquettes with a thermal value of 24783.17 Kcal/kg and fixed carbon value of 8.64% burned slower than those made from plain sawdust with a heating value of 28740.63Kcal/kg and fixed carbon value of 10.15% from Azadirachta indica. There is a significant degree of significance between the groups because the significance values for The percentages of fixed carbon, volatile carbon, ash, and moisture content were all obtained at 0.000, ($p < 0.05$). Discussion: But the purpose of these wood waste briquettes is to inspire people to use them as a substitute source of biofuel; they are bound using easily accessible, reasonably priced, and ecologically benign organic binders. By doing this, the amount of air pollution that enters the environment is reduced. Conclusion: This demonstrates that, in comparison to briquettes made from ordinary Azadirachta indica sawdust, those made from sawdust bound with rice husk exhibited a slower rate of burning. In contrast to other organic binders, Azadirachta indica demonstrated good performance in Melicia Elcelsa, where this study was conducted.

1. Introduction

The highest contribution to the world economy is India. India has the third-highest primary energy consumption in the world, behind the US and China. The three primary fuels are solid biomass, oil, and coal. Coal is the main element driving the growth of industries and the production of power. In India, there are more than 660 million people who have not entirely embraced contemporary, clean cooking methods or fuels. More than half of all trees cut worldwide are utilized for firewood. Compressed sawdust that has been turned into charcoal is used to make the charcoal "Briquettes" that are used in barbecues [9]. New garbage, like wood, is the primary fuel source for a sizable chunk of the nation. India is third globally in terms of CO_2 emissions [10]. Its carbon intensity is far greater than the global average, especially in the energy sector. One of the biggest social and environmental problems in India today is air pollution, which is largely caused by particulate matter emissions. In 2019, household and ambient air pollution caused far over a million preventable deaths.

There are 9 and 166 publications in google scholar and science direct publications about this research because it was conducted utilizing various bio waste or other novel waste products such as hay, coco husk, and rice husk [8], waste paper, cow dung [14], etc. in addition to diverse binding agents like starch [1], arabic gum [15]. Rising fuel prices drove the need for an

alternative biofuel production source with a high combustion capacity [13]. This source also needed to be able to boost its heating efficiency through the application of different types of binders [9] and its associated environmental air pollution [12]. Wood waste, which is produced in vast quantities by the wood industry, is the main source of biofuel [2] including furniture factories and log houses, etc. in situations where novel wastes are not used on their own. This leftover material, known as sawdust, ought to be preserved and utilized as a replacement source of biofuel [11]. It switches out a precious resource for wastage.

Pressed into briquettes, sawdust enhances its heat and combustion properties. The main focus of the research is on the characteristics of sawdust briquettes made with rice husk as a binding agent [5]. This study became necessary due to the growing interest in employing Azadirachta Indica for domestic production. To determine the fixed carbon value of the briquettes, a few elements like moisture content, ash content, and volatile content must be taken into account [14] that is more efficient and reasonable as a fuel. In addition, we'll calculate its Heating value, which, when combined with the mentioned factors, establishes its combustion rate. Thus, when the wood is converted in sawmills, the study looks for a practical way to use sawdust [7]. Compared to fuel wood, briquettes have a number of benefits, including as high heat intensity, ease of use, cleanliness, and a low need for storage space. This lowers manufacturing costs and gets rid of the need to buy kerosene and charcoal.

2. Materials and Methods

2.1. Sample collection

Sawdust from the Azadirachta indica (Neem Tree) was collected in Chennai's Poonamallee neighborhood in order to make briquettes. The briquettes were created and subsequently tested at the environmental biotechnology lab of the Saveetha School of Engineering located in Thandalam, Chennai. With g power set to 80% and previously gathered data, clincalc.com was used to estimate the sample size. The available literature was used to determine the sample size, and N=18 was determined for each group using a 0.05 alpha error-threshold.

In this investigation, two distinct groups were compared. We investigated the simple sawdust and binder combination briquettes' heating efficiency. The sawdust was sun-dried to eliminate any last traces of external moisture before to testing [16]. Using a 25ml silica crucible, 5g of regular sawdust was compacted into a uniform shape to create the first batch of briquettes [3]. In order to create a uniform mixture, 2g of

rice husk (binder) and 3g of regular sawdust are used in a 3:2 ratio for the second batch of briquettes. For every level, three biological and three technical replicates were used.

The same sample underwent proximate analysis to determine its moisture concentration, volatile matter content, and ash content. The sample was roasted in the hot air oven in the microbiology lab of the Saveetha School of Engineering in Chennai to ascertain its moisture content.

Once more heated in a muffle furnace, the sample was analyzed to determine its volatility and ash content.

2.2. Moisture content

Five grams of the material were put in a crucible and weighed to determine its moisture content after being heated to 110°C for thirty minutes in the hot air oven [9]. The moisture content was determined using the formula below:

$$\text{Moisture \%} = ((\text{Initial-Final})/\text{Initial})*100$$

2.3. Volatile content

The same sample is heated in a covered muffle furnace to 950°C for seven minutes in order to ascertain its volatile content. After that, it is weighed [11]. The volatile content is calculated using the formula below:

$$\text{Volatile\%} = ((\text{Amount of sample present-Amount of weighed after cooling})/(\text{Amount of sample present}))*100$$

2.4. Ash content

To determine how much ash is present in a sample, it is taken, placed in an open Muffle furnace for thirty minutes, and then allowed to cool before being measured. The following formula is used to calculate the ash content:

$$\text{Ash\%} = ((\text{Weight of Ash})/\text{Weight of sample present})*100$$

2.5. Fixed carbon

The formula is used to get the fixed carbon value:

$$\text{Fixed Carbon} = 100-(\text{Moisture\%+Volatile\%+Ash\%})$$

2.6. Heating value

The following formula is used to determine the substance's value:

$$Hv = 2.326(147.6c+144v)$$

3. Analytical Statistics

IBM SPSS version 28.0.0.0 was used as the statistical software. The data were subjected to independent T test at a 0.05 level of probability. The Sawdust + Rice husk are the independent variables, the dependent variables are the percentage of moisture, volatile carbon, ash, fixed carbon, and heating value. Additionally, descriptive statistics were applied to the data, including the mean and standard error of the estimates. All analyses were performed utilizing SPSS, a statistical programme [6].

4. Results

Tables 194.1 and 194.2 predict the Heat value and approximate analysis of sawdust and plain sawdust along with Rice Husk. As per the table the average value of Moisture content in plain Saw dust is 12.11% whereas Saw dust + Rice Husk tends to be quite higher at 14.96%. Similarly in case of average Volatile content the Sawdust +Rice Husk showed 65.16% but plain saw dust had a high amount of Volatile content up to 75.57%. The results were not the same when estimating the average Ash content since Plain Sawdust only showed 2.18% while Sawdust + Rice Husk represented approximately 11.23%. Finally, the average Fixed carbon content of plain Saw dust and Sawdust + Rice Husk had decreased value in their differences i.e. 10.15% and 8.64%. The Heating value determined by the mathematical equation led to a decrease in their Heating values of the two samples, with plain Saw dust holding 28740.63 Kcal/Kg whereas Saw dust + Rice Husk held 24,783.17 Kcal/Kg.

The results of the ANOVA evaluation are displayed in Table 194.3, along with the mean, standard deviation, standard error, and number of samples. Table 194.4 shows that, depending on the different proximate analysis parameters, both groups have p values less than.001, indicating statistical significance. A 95%

Source: Author.

confidence interval was used in the study to measure the difference. The comparison of samples of sawdust alone and sawdust combined with rice husk on a range of proximate analytical parameters is shown in Figure 194.1. The comparison between the Sawdust + Rice Husk and Plain Sawdust increases in the computed Heating value is shown in Figure 194.2. The findings showed that, with a heating value higher than that of the plain sawdust sample, the group 2 sample (sawdust with rice husk) had good physical qualities to function as a fuel substitute.

5. Discussion

In this research, Rice Husk in Sawdust was an effective substrate compared to Plain Sawdust for increasing Heating value. As a result, there was an increase in Fixed carbon content of Sawdust along with Rice Husk in comparison with Sawdust. The calculated Heating value for sawdust in the presence of Starch was observed to be more in comparison to Plain Sawdust. This demonstrated that variations in components of Heating value are the consequence of influences from a variety of factors rather than just changes in Fixed Carbon content. According to the results of the analysis, the sample of had reduced moisture content and volatile matter levels. Sawdust + Rice Husk. The Heating value is positively impacted by a drop in Moisture content and Volatile matter along with a tremendous decrease in Ash content. As more Volatile material is present, the rate of ignition and combustion will increase. As these two factors are necessary for a fuel compound. Reduction of Ash percentage and slight decrease in Volatile matter of Sawdust + Rice Husk can increase the Heating value of the substance. This could require a change in the composition ratio of both the mixtures. Hence the Sawdust+Rice Husk briquettes were more effective for alternative fuel briquettes. This definitely demonstrates that Saw dust + Rice Husk briquettes were much more successful when compared to plain Saw dust briquettes.

In the research work of [4], the Average Fixed Carbon, Average Ash Content, and Average Volatile Matter and Heating value was measured for the proximate analysis of three different hardwood species of Africa. The Heating value was calculated for the Plain Sawdust which suggested that 27022.51 Kcal/kg is comparatively more or less than the result of Sawdust + other binders obtained. The comparison with the above listed article also helps us to understand the significant increase in the Heating value of the Sawdust + other binders.

The assessment of the unique waste material briquettes' physical and combustion qualities was the main focus of the current study. Study on the estimation of Calorific value of the substance through bomb calorimeters helps us to estimate its heating efficiency and ignition rate. The crucible and sample must be weighed together in order to acquire precise findings, and the temperature of the Muffle furnace must be kept for seven minutes at 950°C and for thirty minutes at 750°C. This is the research study's limitation. The study's findings aid in the understanding of sawdust's physical and combustion characteristics by the researchers and also helps them to work on the formulation of briquettes. Which is an alternative source for biofuels through natural products.

6. Conclusion

Hence, Saw dust briquettes bound with Starch gave very good results, it also showed us a good value of Heating value, Ash content and Volatile content of Azadirachta indica when compared with Melicia Elcelsa.
